## 14. International Quality Conference Conference manual

**ISBN: 978 - 86 - 6335 - 104 - 2**

**Editors:** *Dr Miladin Stefanović*, full professor  
Faculty of Engineering, Kragujevac  
*Dr Aleksandar Đorđević*, assistant professor  
Faculty of Engineering, Kragujevac

**Technical Editors:** *Dr Hrvoje Puškarić*, higher lecturer  
Academy of Professional Studies Sumadija, Kragujevac  
*Dr Marija Zahar Đorđević*, research assistant  
Faculty of Engineering, Kragujevac

**Publisher:** **FACULTY OF ENGINEERING**  
34000 KRAGUJEVAC  
Sestre Janjić 6

**CENTER FOR QUALITY**  
34000 KRAGUJEVAC  
Sestre Janjić 6

**For publisher:** *Prof. dr Slobodan Savić*

**No. of copies:** 200

**Printing:** *Interprint*, Kragujevac

Publication of Conference manual and organization of  
14. International Quality Conference is supported by:  
**Ministry of Science, Technological Development and Innovation of the Republic of  
Serbia**

Izdavanje Zbornika radova, organizovanje i održavanje  
14. International Quality Conference podržalo je:  
**Ministarstvo nauke, tehnološkog razvoja i inovacija Republike Srbije**

## *14<sup>th</sup> International Quality conference*

### *Scientific Advisory Board*

1. Slavko Arsovski, Faculty of Engineering, University of Kragujevac, Kragujevac, Serbia, president
2. Zdravko Krivokapić, Faculty of Mechanical Engineering, University of Montenegro, Podgorica, Montenegro, vice president
3. Zoran Punoševac, AQS, Kruševac, Serbia, vice president
4. Yury Klockov - Ключков Юрий Сергеевич, Peter the Great St.Petersburg Polytechnic University, Russian Federation

### *Programme Committee*

1. Miladin Stefanovic, Faculty of Engineering, University of Kragujevac, Serbia Peter the Great St. Petersburg Polytechnic University, president,
2. Aleksandar Đorđević, Faculty of Engineering, University of Kragujevac, vice-president
3. Aleksandar Vujović, Faculty of Mechanical Engineering, University of Montenegro, Podgorica, Montenegro, co-president, Montenegro
4. Abd-Elrahman, Ain Shams University Faculty of Commerce, Cairo, Egypt
5. Aleksei V. Bogoviz - Independent researcher, Moscow, Russia
6. Ali Ahmadi Awwad Rawabdeh, Faculty of Economics and Administrative Sciences, Yarmouk University, Irbid, Jordan
7. Alina-Andreea Dragoescu Urlica, U.S.A.M.V.B. Timișoara, România
8. Ayşegül Akdoğan Eker, Yıldız Technical, University Mechanical Faculty, Beşiktaş/İstanbul, Turkey
9. Bojan Lalic, Faculty of Technical Sciences, University of Novi Sad, Serbia
10. Bruno S. Sergi - Harvard University, USA and University of Messina, Italy
11. Bülent Eker, Namık Kemal University, Tekirdağ, Turkey
12. Changiz Valmohammadi, Taylor's University, Malaysia
13. Cristiano Fragassa, Alma Mater Studiorum Università di Bologna, Italy
14. Elena G. Popkova - Leading researcher of the Center for applied research of the chair "Economic policy and public-private partnership" of Moscow State Institute of International Relations (MGIMO University), Russia

15. Evandro Eduardo Broday, Federal University of Technology Paraná, Paraná, Brasil
16. Ezendu Ariwa, London Metropolitan Business School, London Metropolitan University, UK
17. George F. Fragulis, Western Macedonia University of Applied Sciences, Kila, Greece
18. Goran Putnik, University of Minho, Braga, Portugal
19. Ibrahim Badi, Department Mechanical Engineering, Misurata University, Misurata, Libya
20. Iñaki Heras, Universidad del País Vasco, San Sebastian, Spain
21. Jelena Sakovic Jovanovic, Faculty of Mechanical Engineering, University of Montenegro, Podgorica, Montenegro
22. Jovan Filipovic, Faculty of Organizational Sciences, University of Belgrade, Serbia
23. Krešimir Buntak, University North, Koprivnica-Varaždin, Croatia, Croatia
24. Lula Paweł, Cracow University of Economics, Poland
25. Martí Casadesús, AQU Catalunya, Barcelona, Spain
26. Michael Olarewaju Ogundele, Department of Education Foundations, Faculty of Education, University of Jos, Jos, Nigeria
27. Milan Erić, Faculty of Engineering, University of Kragujevac, Serbia
28. Miodrag Lazić, Faculty of Engineering, University of Kragujevac, Kragujevac, Serbia
29. Muafi, Universitas Islam Indonesia Yogyakarta, Indonesia
30. Nenad Simeunovic, Faculty of Technical Sciences, University of Novi Sad, Serbia
31. Nikola Stefanovic, Singidunum University, Beograd, Serbia
32. Norizan Kassim, University of Nizwa, Oman
33. Pablo Cabanelas, University of Vigo, Spain
34. Paul M. Andre, AQE Group, Chicago, Illinois, USA
35. Prasun Das, SQC & OR Division of the Indian Statistical Institute (ISI), Kolkata, India
36. Samuel Fosso Wamba, Toulouse Business School, Federal University of Toulouse Midi-Pyrénées, Toulouse, France
37. Stanislav Karapetrović, University of Alberta, Edmonton, Canada
38. Tadeja Jere Jakulin, University of Primorska, Koper, Slovenia
39. Tadeusz Sikora, The Department of Quality Management, Cracow University of Economics, Kraków, Poland
40. Ugljesa Marjanovic, Faculty of Technical Sciences, University of Novi Sad, Serbia
41. Vesna Spasojevic Brkic, Faculty of Mechanical Engineering, University of Belgrad, Serbia
42. Vladimir Senic, Faculty of Hotel Management and Tourism, University of Kragujevac, Serbia

43. Zora Arsovski, Faculty Of Economics, University of Kragujevac, Kragujevac, Serbia
44. Roman Tsarev, International Academy of Science and Technologies, Moscow, Russian Federation
45. Ionel Bostan, Cuza University, Romania
46. Danijela Ćirić Lalić, Universty of Novi Sad, Serbia
47. Anurag Hazarika, Tezpur Central University, India
48. Dinh Tran Ngoc Huy, International University of Japan, Japan
49. Samrad Jafarian-Namin, Yazd University, Iran
50. Yakuthan K. Karrieva, Tashkent State University of Economics, Tashkent, Uzbekistan
51. Shakhlo T. Ergasheva, Tashkent State University of Economics, Tashkent, Uzbekistan
52. Zorana Tanasić, University of Banja Luka Faculty of Mechanical Engineering, Banja Luka, Bosnia and Herzegovina

QUALITY  
RESEARCH **International Quality Conference**

---

*Dear friends,*

*By providing international platform, 14. International Quality Conference 2023 will gather experts from industry and academia in order to exchange ideas and present results of ongoing research in a range of topics.*

*This Conference has a motto "Quality, education, and innovation, the path to sustainable success".*

*We invite you to participate in this important event.*

*Sincerely yours,  
President of Organization Committee*

*Prof. dr Miladin Stefanovic*

*Mirjana Cvečković*

## **CONTENT BOOK 1:**

### **PLENARY SESSION .....1**

1. Slavko Arsovski  
THE SUSTAINABLE TRANSITION FROM QUALITY 4.0 TO QUALITY 5.0. A  
ROLE OF SUSTAINABLE SPIRITUAL AND INTELLIGENT LEADERSHIP IN THE  
CREATION OF INTANGIBLE CAPITAL FOR FUTURE.....3
2. Leonilde Varela, Goran Putnik, Gaspar Vieira, Vijaya Kumar Manupati, Cátia Alves  
GROUP D-M APPROACH FOR RANKING AND SELECTING MAINTENANCE  
TASKS FOR JOINT SCHEDULING WITH PRODUCTION ORDERS.....21
3. Andres Carrion, Jose Jabaloyes, Patricio Montesinos, Manuel Martinez  
EMOI: AN INNOVATION MANAGEMENT MODEL PROPOSAL.....47
4. Tamara Papić, Tadeja Jere jakulin  
SYSTEM THINKING FOR BUSINESS MODEL INNOVATION .....57
5. Pavel Shcherban, Mazur Ekaterina Vladimirovna  
PRELIMINARY ASSESSMENT OF THE TECHNICAL CONSEQUENCES OF THE  
INCIDENTS ON THE NORD STREAM 1 AND 2 GAS PIPELINES. POSSIBLE  
WAYS OF SOLVING THE PROBLEMS .....67
6. Elsayed A. H. Elamir, Gehan A. Mousa, Abdelmohsen M. Desoky, Alaa Garad  
THE BIDIRECTIONAL RELATIONSHIP BETWEEN HIGHER EDUCATION AND  
INNOVATION: EMPIRICAL EVIDENCE FROM MENA REGION .....81
7. Aleksandar Rikalovic, Bojana Bajic  
ROAD TO INDUSTRY 5.0: CHALLENGES AND OPPORTUNITIES.....99

### **SCIENTIFIC FOCUS 1: QUALITY, BROAD PERSPECTIVE.....109**

8. Slavko Arsovski  
QUALITY 5.0: FROM CHALLENGES TO REALITY .....111
9. Forough Farhadi Cheshmeh Morvari, Imadeddine Oubrahim, Ikram Ahidar  
A CONCEPTUAL REVIEW OF DIGITAL TWIN-BASED BUSINESS ECOSYSTEMS  
IN SUPPLY CHAIN PLANNING .....123
10. Miloš Jelić  
STRATEGIC DECISION-MAKING OF ORGANIZATION IN VOLATILE BUSINESS  
ENVIRONMENT .....133

11. Marjetka Kastner, Mirjana Ivanuša Bezjak, Mojca Babuder BUSINESS PROCESS IMPROVEMENT - IMPROVEMENT OF INTERNAL CERTIFICATION PROCESSES .....	141
12. Vladan Paunović, Sanja Puzović, Zoran Nešić, Jasmina Vesić Vasović USE OF INTEGRATED MCDM APPROACH FOR THE SELECTION OF LEAN TOOLS TO IMPROVE THE ORGANIZATIONAL-BUSINESS PERFORMANCE .....	153
13. Aleksandra Jovičić, Marija Savković, Miladin Stefanović, Ivan Mačužić, Nastasija Nikolić THE IMPACT OF HORIZONTAL AND VERTICAL SYSTEMS INTEGRATION ON QUALITY 4.0 .....	161
14. Marek ŹJabłoński, Anna Prusak THE APPLICATION OF AHP IN ASSESSING QUALITATIVE ASPECTS OF WORK: A CASE STUDY OF A MUNICIPAL COMPANY .....	169
15. Jelena Jovanović AN APPROACH FOR BUSINESS-MANUFACTURING SYSTEMS MODELING IN ORDER TO APPLY OPTIMIZATION PROCESSES .....	177
16. Dariusz Ras THE NEW MULTICRITERIA-BASED MODEL FOR QUALITY ASSESSMENT OF WRITTEN MEDIA MESSAGES - PERSPECTIVES FOR APPLICATION ....	185
17. Getahun Mekuria ASSESSMENT OF SERVICE QUALITY USING SYNERGIES OF FUZZY SERVQUAL, FUZZY KANO'S MODEL, AND FUZZY ANALYTIC NETWORK PROCESS INTO QFD .....	193
18. Nikita Tsygankov, Anastasia Petrunina, Alexander Moskalev, Anatolii Vershkov SYSTEM OF BALANCED INDICATORS FOR NEW PRODUCT DEVELOPMENT STRUCTURES TAKING INTO ACCOUNT CUSTOMER SATISFACTION .	227
19. Tamer Haddad QUALITY EVALUATION OF CONCRETE BLOCK FOR WALLS PRODUCTION USING STATISTICAL PROCESS CONTROL (SPC) TOOLS: A PALESTINIAN CASE STUDY .....	239
20. Sudaryanto Sudaryanto, Sisira Colombage, Bambang Irawan, Anifatul Hanim, Ivana Rosediana Dewi THE LOW-QUALITY INFLUENCE OF PURCHASING: THE CASE OF FASHION STORES IN INDONESIA .....	253
21. Ashwin Singh Chouhan, Riya Raisinghani, Anam Khan, Arshi Khan, Manish Solanki, Arshi Khan A CASE STUDY ON THE SURVEY BASED RESEARCH OF CUSTOMER'S CHOICE OF TOOTHPASTE IN RAJASTHAN'S POPULATION .....	267
22. Diah Yulisetiarni, Desiyah Rhamadani Damayanti, Ariwan Joko Nusbantoro THE EFFECT OF PRODUCT QUALITY AND STORE ATMOSPHERE ON CUSTOMER LOYALTY THROUGH CUSTOMER SATISFACTION AT ALFAMART JEMBER .....	279

23. Chandrakala V G, Sowmya C U, Nagesha H G  
 A STUDY ON FACTORS INFLUENCING THE CONSUMER BUYING BEHAVIOR  
 WITH REFERENCE TO ORGANIZED APPAREL RETAIL OUTLETS .....291
24. Fandy Setya Gamaliel, Nina Nursida, Nida Amalia, Syahrial Shaddiq, R . Rudi Alhemp,  
 Lalu Supardin  
 THE EFFECT OF COMPANY SIZE AND CORPORATE GOVERNANCE  
 MECHANISMS ON PROFIT MANAGEMENT ACTIVITIES IN INDUSTRY 4.0  
 .....301

**SCIENTIFIC FOCUS 2: QUALITY ENGINEERING AND  
 MANAGEMENT.....313**

25. Enriko Ceko  
 ON THE RELATION BETWEEN ENTREPRENEURSHIP AND QUALITY  
 MANAGEMENT .....315
26. Minwir AlShammari, Saleh Isa  
 AN INVESTIGATION INTO TQM IN A RETAIL BANK IN THE KINGDOM OF  
 BAHRAIN.....329
27. Vartharaj Chetty, Sugandren Naidoo  
 INTEGRATING CONSTRUCTS OF THE TECHNOLOGY ACCEPTANCE MODEL  
 AND TOTAL QUALITY MANAGEMENT TO IMPROVE DOCUMENT  
 MANAGEMENT PERFORMANCE .....335
28. Eka Rakhmat Kabul, Raden Rudi Alhemp, Satriadi Satriadi, Ranti Utami, Rachmad  
 Chartady, Syahrial Shaddiq  
 INDEX SCALE OF TOTAL QUALITY MANAGEMENT IMPLEMENTATION ON  
 THE PERFORMANCE OF MSMES PRODUCERS OF GRC .....361
29. Fatma Lehyani, Alaeddine Zouari  
 HOW DO TQM PRACTICES AFFECT EMPLOYEE EFFECTIVENESS IN TUNISIAN  
 SMES? .....371
30. Jovana Nikolić, Miladin Stefanović, Nikola Simić  
 DEVELOPMENT OF A FRAMEWORK FOR DEFINING THE CONCEPT OF  
 QUALITY 4.0 .....383
31. Mueyyed Akram Omar Arslan, Sivadass Thiruchelvam, Gasim Hayder  
 THE AVAILABILITY OF THE DOCUMENTATION REQUIREMENT TO OBTAIN  
 THE ISO 9001:2015 CERTIFICATE IN PREFABRICATED BUILDING FACTORY-  
 IRAQ: A CASE STUDY .....395
32. Getahun Mekuria  
 AN EMPIRICAL INVESTIGATION ON THE PERFORMANCE OF THE  
 COMPONENTS OF QUALITY MANAGEMENT: IN THE CASE OF ETHIOPIAN  
 MANUFACTURING COMPANIES .....407

33. Abdurrahman Abdurrahman, Awliya Afwa, Rofifah Fhadilla Bakris, Syahrial Shaddiq, R. Rudi Alhempri THE INFLUENCE OF DIGITAL MARKETING ON CONSUMER BUYING INTEREST ON SHOPEE MARKETPLACE IN SOCIETY 5.0 (PEKANBARU CITY STUDENT CASE STUDY) .....	421
34. Jovan Šofranac, Vuk Petronijević, Nebojša Abadić MODEL OF DEVELOPMENT AND IMPLEMENTATION OF IMS .....	431
35. Davor Grgurovic OVERVIEW OF RISK MANAGEMENT TOOLS AND METHODS .....	441
36. Jovan Šofranac, Vuk Petronijević, Nebojša Abadić THE IMPACT OF QUALITY COSTS ON THE LEVEL OF IMS MATURITY .....	449
37. Mohsen Anvari, Abolghasem Anvari, Alireza Anvari EVALUATING SCOR METRICS OF SUPPLY CHAIN PERFORMANCE BASED ON INVENTORY MANAGEMENT .....	457
38. Zorica Lazic, Milica Grujic, Vladimir Skoric, Srdjan Milicevic IMPACT OF GLOBAL CRISIS ON SUPPLY CHAIN MANAGEMENT QUALITY: CASE STUDIES .....	479
39. B Vanishree, T S Nanjundeswaraswamy, D R Swamy MODELLING CRITICAL SUCCESS FACTORS OF GREEN SUPPLY CHAIN MANAGEMENT-AN INTEGRATED APPROACH OF PARETO, ISM AND SEM .....	489
40. Maciej Urbaniak, Dominik Zimon EXPECTATIONS TOWARDS SUPPLIERS IN TERMS OF ENSURING AND IMPROVING THE QUALITY OF PRODUCTS AND PROCESSES .....	515
41. Eka Rakhmat Kabul, Romandus Hamonangan, R. Rudi Alhempri, Satriadi, Tubel Agusven, Syahrial Shaddiq ANALYSIS OF CUSTOMER SERVICE QUALITY MANAGEMENT IN IMPLEMENTATION OF TSM KODAWARI AT TAM WORKSHOP .....	523

**SCIENTIFIC FOCUS 3: QUALITY AND INDUSTRY .....537**

42. Olga Safonova, Vladimir Konyukhov ENSURING THE COMPETITIVENESS OF INDUSTRIAL ENTERPRISES BASED ON METHODS FOR ASSESSING THE QUALITY OF INDUSTRIAL PRODUCTS .....	539
43. Vesna Spasojević Brkić, Branislav Tomić, Martina Perišić, Ivan Mihajlović, Nemanja Janev QUALITY TOOLS AND METHODOLOGIES INFLUENCING THE INVESTMENT AND DEVELOPMENT PERFORMANCE IN AEROSPACE INDUSTRY COMPANIES OF THE EUROPE AND NORTH AMERICA .....	549
44. Slobodan Malbašić, Bogdan Nedić, Aleksandar Đorđević, Srđan Živković THE ROLE OF THE COST AND QUALITY IN ADDITIVE MANUFACTURING .....	563

45. Marija Savković, Miloš Petrović, Carlo Caiazzo, Marko Đapan, Arso Vukićević  
 DETERMINE MUSCLE STRAIN OF ASSEMBLY WORKERS BY APPLYING  
 ADVANCED EMG MEASUREMENT.....573
46. Jovana Nikolić , Miladin Stefanović, Marko Đapan  
 INDUSTRY 4.0 AND INDUSTRY 5.0 – OPPORTUNITIES AND THREATS 585
47. Strahinja Djurović, Dragan Lazatević, Milan Mišić, Jelena Stanojković, Bojan  
 Stojčević, Jasmina Dedić  
 ADVANTAGES AND DISADVANTAGES OF TECHNIQUES AND PROCESSES OF  
 3D PRINTING IN INDUSTRIAL APPLICATION .....597
48. Osman Mohamedyasin, Yasir Osman, Ramesh B. Aremanda  
 CONCEPTUAL REVIEW ON THE NECESSITY OF 3D PRINTING FEATURED  
 CONSTRUCTION IN ERITREA .....611
49. Gligorije Mirkov, Mirko Đapić  
 ROUTING FLEXIBILITY ANALYSIS OF DIDACTIC FLEXIBLE  
 MANUFACTURING CELLS USING EVIDENCE NETWORKS .....625
50. Nemanja Pajić, Jovana Aleksić, Fatima Živić, Aleksandar Đorđević  
 AI APPLICATION IN QUALITY ASSURANCE OF INDUSTRIAL LASER  
 WELDING PROCESSES .....637
51. Vladimir Stanislavovich Fetisov, Dmitry Dmitriyevich Kudashov, Alexey Vladimirovich  
 Ovchinnikov, Kseniya Olegovna Novikova  
 STUDY ON OPEN CONTACT SYSTEMS WITH FLAT PARALLEL ELECTRODES  
 FOR AERIAL ROBOTS CHARGING PLATFORMS.....647
52. Predrag Mitić, Marija Zahar Đorđević, Vuk Petronijević, Nebojša Abadić, Aleksandar  
 Đorđević  
 AUTOMATIC TOOL PATH GENERATION IN CONTOUR MILLING USING  
 GENETIC ALGORITHM .....663
53. Đorđe Mijailović, Aleksandar Đorđević, Miladin Stefanović, Milan Erić  
 QUALITY CONTROL IN THE MANUFACTURING INDUSTRY BASED ON THE  
 APPLICATION OF COMPUTER VISION.....681
54. Haitam Ettazi, Hamza Mocket, Jaafar Abouchaba  
 DETECTION AND RECOGNITION OF ROAD SIGNS USING YOLOV5 .....689
55. Đorđe Mijailović, Aleksandar Đorđević, Miladin Stefanović, Milan Erić  
 IDENTIFICATION OF PRODUCT NON-CONFORMITIES USING COMPUTER  
 VISION ALGORITHMS .....699
56. Ramesh B. Aremanda, Hanna Biniam, Heran Alazar  
 SIMULATION OF LIQUEFACTION OF NITROGEN RICH GASEOUS EMISSIONS  
 FROM THE OXYGEN PRODUCTION PLANT.....709
57. Pavel Makarikhin, Anastasiya Grigorieva, Margarita Maksimenko  
 CLUSTERING OF LOCALIZED ACOUSTIC EMISSION SOURCES BY THE  
 DBSCAN ALGORITHM IN SEPARATORS .....725
58. Vladimir Khmelev, Roman Barsukov, Aleksandr Barsukov  
 CONTROL OF THE ULTRASONIC EMITTERS PARAMETERS TO DETERMINE  
 THE DEGREE OF TOOL MATERIALS AND PROTECTIVE COATINGS  
 CAVITATION DESTRUCTION.....735

59. Anatoliy Plakhtiev, Elshod Nabiyev, Yashnarjon Aliev, Ravshan Boboyorov, Yahyojon Meliboev, Dildora Jalolova, Akmal Durmanov  
 MAIN CHARACTERISTICS OF NONCONTACT CONVERTERS OF LARGE CURRENTS WITH LONGITUDINALLY DISTRIBUTED PARAMETERS FOR CONTROL AND MONITORING SYSTEMS .....749

## THE SUSTAINABLE TRANSITION FROM QUALITY 4.0 TO QUALITY 5.0: A ROLE OF SUSTAINABLE, SPIRITUAL AND INTELLIGENT LEADERSHIP IN CREATION OF INTANGIBLE CAPITAL FOR FUTURE

**Abstract:** *A world is in process of rapid changing in all areas of living. In all of them exists old and new problems with urgent needs for solving. Transition from Industry 3.0 to Industry 4.0 changed view on industry in 21st century and also there are challenges based on Quality 3.0 and Quality 4.0 concept. In last ten years is developed concept of Japan's „Society 5.0“ which needs Quality 5.0 concept. This is main motive for researching possibility for transition quality into Quality 5.0 concept. In the paper are presented basic information about Industry 4.0 and Quality 4.0 based on new challenges in 21st century. Based on literature and own research is defined concept of Quality 5.0 and ways of transition to Quality 5.0, specially in transition counties as Serbia in next 30 years. The first analysis pointed out that it is possible with using intangible capital-including smart technologies, smart leadership, smart people and other smart „things“ for achieving smart/integrated quality, quality of life, resilience and all human-centric activities. The new concept of Quality 5.0 needs new role of leadership (Sustainable, Spiritual, Intelligent Leadership), the new model of the effective transition from Quality 4.0 to Quality 5.0 and creating quality capital needed for the future.*

**Keywords:** *Transition from Quality 4.0 to Quality 5.0. Sustainable, Spiritual and Intelligent Leadership, Intangible capital, ANN, DEA, Grounded theory, Reframing organizations*

### 1. Introduction

A digital future is started in 21. century and in four waves Tompston N. (2014) is recognized as key for resolving different socio technological challenges. It practically means that is necessary to review existing and create new business models and paradigms as. (1) Sustainable Intelligent, and Spiritual Leadership (SISL), (2) Industry 4.0,

(3) Quality 4.0, (4) Quality 5.0 and (5) intangible for its transition.

In new digital era business and social environment is also changing because concepts of Industry 4.0 and Society 5.0 need new view of a future of civilization. Now is necessary to include redesigned old and created new paradigms related to intangible capital as: SISL capital, knowledge capital, intellectual capital and

---

Corresponding author: Slavko Arsovski  
Email: [cqm@kg.ac.rs](mailto:cqm@kg.ac.rs)

other with mutual impact on quality and society as whole. In area of leadership are developed Intelligent Leadership, ICT Leadership, Cultural Leadership, Shared Leadership, Team Leadership, Change Leadership, Ethical Leadership, Complexity Leadership, Smart Leadership, Virtual Leadership and so on.

In Industry 4.0 concept of fourt industri revolution dominant role have smart technologies, smart manufacturing, smart factories (enterprises), cyber-physical systems, cloud manufacturing, Internet of Things (IoT), and others.

Related to concept of Industry 4.0 is developed concept of Quality 4.0 which covers aspects of technologies for quality, human resources for quality and processes related to quality. These aspects are analyzed in future chapters using identified sub-variables.

In concept Quality 5.0 defined by works of Arsovski S. (2019) are included soft factors related to cultural, social and eco-environment. On maturity top level of Quality 5.0 impact has a man with his spiritual, biological and social performances.

A capital needed for efficient and effective transition from Quality 4.0 to Quality 5.0 is key for this transition. For it is more important intangible capital. All emphasized factors are more detailed described in next chapters.

The purpose of the research presented in the article is to integrate a key enablers for efficient and effective transition from Quality 4.0 to Quality 5.0 in a Enterprises.

The goal of presented research is threefold, i.e.. (1) defining concept of SISL, (2) defining model of smart transition from Quality 4.0 to Quality 5.0, and (3) simulate impact of SISL and maturity level of Quality 4.0 on Quality 5.0 concept in praxis..

In the presented research are used the new research model with four independent variables (SISL), Quality 4.0 maturity,

Intangible capital, and Quality 5.0 as dependent variable. For creating the model is used Grounded theory, reframing organization concept and Process Modeling approaches.

The theoretical novelty includes: (1) model of transition from Quality 4.0 to Quality 5.0, (2) defining SISL, (3) analysis of key enablers in the proposed model using statistical methods Artificial Neural Network (ANN) and DEA methods for predicting the success of transition.

The practical novelty are results of case study based on research of 235 enterprises in potential for the transition and simulation of impact of key enablers on transition process.

## **2. Literature review**

The literature review is made based on levels of maturity of new quality concepts (figure 1). Among them are common areas and time for resolving dilemas, goals, needed intangible capital and so on. In Serbia, as developing cantry, dominant role has Quality 3.0 concept in last ten years. The process of transition to Quality 5.0 is very complex and is described partly in literature with emphasizing soft factors as SISL and intangible capital.

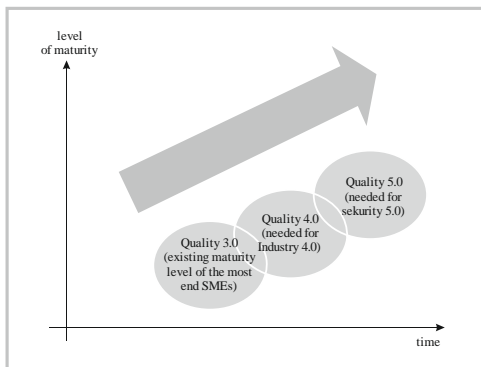

The first identified variable in the model is SISL related to new role of leadership.

A leadership in the digital age according Khan S. (2016) has three interconnected concepts i.e.: (1) value based leadership, (2) transformational leadership, (3) autentic leadership.

Fry L. (2016) defined model of spiritual leadership with impact on spiritual well-being and triple botton line. It starts from hope/vision, inner life and altruistic love. In the middle of the model are calling and membership. At the end are life satisfaction, social responsibility, performance excellence, organizational productivity, organizational

commitment, and employee engagement.

Fry I. And Matherly L. (2006) in one exploratory study analyzed spiritual leadership and organizational performance on the proposed model, using SLT survey questions they find high correlation among variables: (1) hope/faith and altruic love, vision, (2) vision to altruistic love and calling meaning, (3) meaning/calling for achieving sales, organisational commitment, (4) membership to organizational commitment and productivity).

**Figure 1.** Levels of maturity

For new age in the work of Khan S. (2016) are proposed perspectives of holistic leadership, virtual leadership and hub-and networked-based leadership.

Sustainable leadership is based on theory of sustainability through three types of indicators: (1) economic, (2) social and (3) environmental in different business and social areas (Brandt E., 2016; Malik H., Mahmood M., 2022., Kanters N., 2013). According standard ISO 9004:2009 are emphasized five maturity level, i.e.: (1) the leadership is reactive and based on top-down instructions, (2) leadership is reactive and based on decisions by managers at different organisation levels, (3) leadership is proactive and the authority to take decisions is delegated, (4) leadership is reactive with high involvement of the employees in

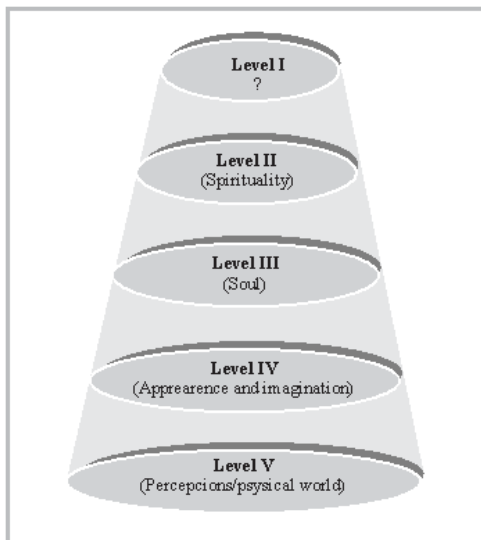

decision making, (5) leadership is reactive and learning-oriented with the empowerment of people at all levels. In this standard a sustainable structure is related to following components used for the own research: (SS1) organizational effectiveness for achieving desired sustainable levels, (SS2) knowledge and skills of the staff, (SS3) motivation of the staff and (SS4) social, environmental, legal and business pressures for achieving desired level of sustainability.

Intelligent leadership is concept developed for intelligent organizations, as organizations in concept Industry 4.0 (Sydänmaanlakka P., 2003). In proposed leadership model a intelligent leadership can be defined as follows: „Intelligent leadership is a dialoge between leader(s) and folowers where they come together in a certain situations in order to achieve shared vision (purpose) and take place in a certain team and organization which is shaving same values and culture. The macro environment-industry and society-also affects this process“. On this way is possible to achieve an efficient, learning and well-being organization. For this role of leaders have to develop a lot of new competences, including digital oriented knowledge, artificial intelligence, orientation to change, what is used as components for own research.

Spiritual leadership (SL) is developed as incorporation of spirituality into leadership concept (Burke R., 2006). He analyzed different aspects of leadership and introduced role of spirituality which included ethical, responsible sustaining, hope inspiration and purpose. Fry L. and Kriger M. (2009) introduced term spiritual intelligence as a very general mental capability that, among other things, involves the ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly and learn from expirience. It is not merely book learning, a narrow academic skill or test-taking smarts. Rather, it reflects a broader and deeper capability for

comprehending our suproundings – „catching on“, „making sense“ of things, or „figuring out“ that to do.

All of them are used as components SL They made hierarchy with five levels of spiritual intelligence: (5) the sensible/physical world, (4) images and imagination, (3) the soul, (2) spirit, and (1) SQ based on in the nondual in oneness and constant reconcillation of apparent opposities (figure 2).

**Figure 2.** Levels of leadership and human being

### 2.1. Performances related to Industry 4.0

According study of Deloitte (2008) the fourth industrial revolution (Industry 4.0) has four main carracteristics:

1. Vertical networking of smart production systems,
2. Horizontal integration using a new generation of global value-creation network with integration of business processes in business environment (business partners, customrs, new global business and cooperation models),
3. Engineering throughtout the entire value chain in the entire product life

cycle,

4. Acceleration through emerging technologies capable for mass-market applicatia with increased compatitivity based on productivity, security, safety, reducing risks and vulnerability, quality etc.

Government has to promote to radical innovation, as conditio sine qua non for long term competivity and sustainability (Kelly R., 2019). using bibliometric and bibliographic analysis they identity research fields and stage of growth necessary for radical innovation.

An Industry 4.0 environment exists with smart enterprise in center connected with after smart elements as: smart mobility, smart grid, smart logistics, smart buildings, smart homes, social web, business web, cyber-physical production systems (CPPs), and smart people with smart specialization. On the periphery are: Internet of things, Internet of services, Internet of people, and Internet of data.

In study of Deloitte (2018) are analyzed Switzerland readiness for Industry 4.0. On scale 1 – 5 in most enterprises are reorgnized needs for digital transformation to Industry 4.0 (more then 80%), but feeling the impact in company on Industry 4.0 were between 3 – 4 (more then 52% ansvers), high involvement of customers in process transformation into Industry 4.0 (more than 67%), middle range of resource efficiency for analyzing production process (between 2,3,4 about 75%), and high cyber risk (more than 86% of ansvers). Also, dominant current transformational segments and future potential on scale 1-5 were highest in: (1) research and development 43%, (2) procurement and purchasing -39%, (3) production (30%), worchonsing and logistics -26%, (4) marketing -29%, (5) sales -39%, (6) services -45%, and internal enterprise administration -26%. in this transformation is emphasized innovation processes, corporate venturing and the learning

organization with higher role of leadership based on knowledge and motivation of employees.

All of previous sub-variables are related to global characteristics of Industry 4.0: (1) vertical networking, (2) horizontal integration, (3) through-engineering, and (4) acceleration through exponential technologies (Deloitte, 2018). On global business scene are lot new and old aspects and variables related to global business environment, as global competitiveness, opportunities and threats, resource used, future potential of the market, new technologies etc.

A global economy has different names according main goals. So knowledge economy (Saisana M., Munda G., 2008) defined measures and drivers for it for EU countries. They emphasized key indicators: (1) production and diffusion of IT, (2) human resources, skills and creativity, (3) knowledge production and diffusion, (4) innovation, entrepreneurship, creative production, (5) economic outputs, (6) social performance, and (6) internationalisation. All of them is included in proposed model of smart enterprise because knowledge is included in concept of smart enterprise.

## 2.2. Literature review of Quality 4.0/Quality 5.0 concepts

According Jacob D. (2017) research in a Quality 4.0 has 11 axes, i.e.:

1. data,
2. analytics,
3. connectivity,
4. collaboration,
5. application development,
6. scalability,
7. management systems,
8. compliance,
9. culture,
10. leadership, and
11. competences.

On this approach Quality 4.0 is transformed in CIA (Connectedness, Intelligence, and

Automation). In focus of this system are Neural Networks and Deep Learning. Mourtzis D. et al. (2019) emphasized aspects of internal and external complexity and relations in Cyber-Physical Systems) of Industry 4.0.

Relations among Quality management in the 21st Century and Industry 4.0 are analyzed in work of Gunasekaran A., Subramanian N., and Ngoi E. (2018) with emphasized following quality topics for Industry 4.0, i.e.:

1. economic aspects,
2. decision models for quality,
3. business model with integrated quality,
4. human aspect in quality (including leadership and culture), and
5. technological aspects in quality.

In smart society is higher role of ethical and well-being aspects. Ethical government realizes through: (1) impact of regulatives, (2) regulation of collective actions, (3) building/modernising existing regulation, (4) anticipating strength of transformation of collective adaptive systems (ACS), (5) balancing government decisions, (6) deciding adaptive government, etc.

Transition of concept Industry 4.0 to Society 5.0 has impact on planning big social transformation in Japan with destroying five walls related to:

- ministries/agencies,
- legal system,
- technology,
- human resources and
- social acceptance.

A transition from Industry 4.0 to Industry 5.0 is practically transformation of digital manufacturing to digital society (Skobelev P.O., Borovik S.Y., 2017) with convergence of science and technologies in society 5.0 from technology to society.

A concept of enterprise value management defined for smart enterprise in Industry 4.0 could be make broader for Society 5.0 and Quality 5.0 (Fujitsu Consulting, 2002).

According Kearney A.T. (2017) value dimensions from converging technologies have levels:

- value for the factory,
- value to the firm (enterprise),
- value to the industry,
- value to society, and
- value to the individual.

In all of the levels are included elements of Quality 4.0 (level 1, 2 and 3) and Quality 5.0 (level 4 and 5).

Kueper D. et al. (2019) analyzed Quality 4.0 and concluded that cca 63% companies had not decision or plan for it, but only 16% had some form of implementation. The challenges of implementation were: (1) cost of quality check, (2) first-pass yeald, (3) defect rate, (4) rework rate, (5) on-time delivery, (6) customer satisfaction, (7) warranty claims, and (8) product-related complaints. All challenges are base for Quality 4.0 and Quality 5.0, also on levels 1 and 2 in value creation.

### 2.3. Literature review of intangible capital needed for sustainable transition from Quality 4.0 to Quality 5.0

A intangible capital resources needed for sustainable transition from Quality 4.0 to Quality 5.0 consist from: (1) human capital, (2) cognitive capital, (3) intellectual capital technologies, (4) scienction capital, (5) social capital, (6) financial capital, (7) environmental capital, (8) spiritual capital, etc.

According Deloitte (2019) Global Human Capital Trends are emphasized trend importance for industry: (1) learning, (2) human expirience, (3) leadership, (4) talent mobility, (5) HR cloud, (6) talent access, (7) rewards, (8) superjobs, (9) teams, and (10) alternative workforce.

According Deloitte (2015) a digital transformation included intangible capital for improvement of competitivity flexible customer integration and boosting quality

and efficiency, as well as ICT infrastructure, now forms of marketing etc.

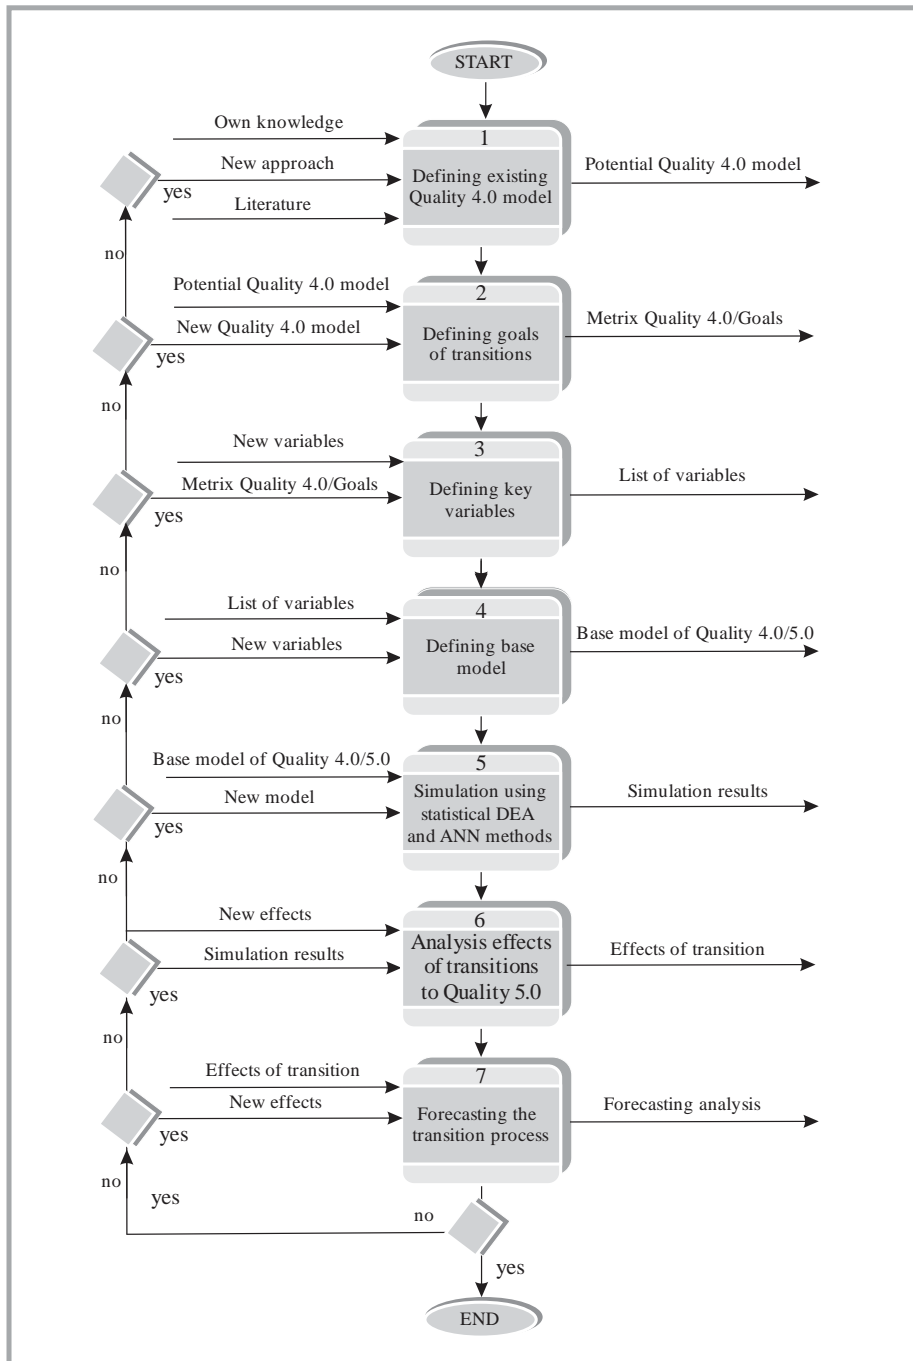

Smart and intelligent technologies cover data technologies smart-production technologies, artificial intelligence, cubersecurity technologgiies, IoT, etc. Other resources are described in broder literature (Hunter I., Webster E., Wyatt A. 2005; Rosman M.I., Nor L.A., Zizah C.S. 2010; Sharon S. (2015); Marphy E. (2022); Noghiu A.A. (2015); Mantog A.M. (2021); Prett T., Shaw E., Dodd S.D. (2016); Gloor P. (2017); Mc Carter B., White B. (2013); Sydanmaanlakka P. (2003); Hazan E. et all. (2021); Sullivan P. JR., Sullivan P. SR. (2000).

### 3. The proposed methodology

The proposed methodology has purpose to: (1) define process of transition from Quality 4.0 to Quality 5.0, based on analysis of existing Quality 4.0 model and goals of transition, (2) definining the key variables for assessment levels of Quality 4.0 and Quality 5.0 based on Grounded Theory (Glaser, Straus, 2006), (3) defining the base model for transition, (4) assessment values of the key variables, (5) simulation effects of transition using statistical methods, DEA (Data Anvelope Analysis) and ANN (Artificial Neural Network), (6) analysis effects of transition to Quality 5.0 and (6) forecasting the transition process in the future. It is presented in Figure 3.

The first step is deefining existing Quality 4.0 using literature presented in previos chapter. Based on it is proposed es autcome potential Quality 4.0 model based on work by Jacob D. (2017) with 11 axes (variables). The key sub-variables is level of Quality management system in broad sense. In second step is defined goals of transition from Quality 4.0 to Quality 5.0 and as autcomes is recognised metrix Quality 4.0/goals. In our research this metrix is presented in Table 1 with assessed weight of component goals.

**Figure 3.** Model of transition Quality 4.0 to Quality 5.0

**Table 1.** Matrix of axis/goals for Quality 4.0.

No of axes	Goals					
	Quality level	Relation with customers	Integration with Industry 4.0	Social responsibility	Reduction resources	Higher safety and security
Data	10	5	10	5	5	5
Analytics	5	5	10	5	5	5
Convertivity	5	5	10	5	5	5
Collaboration	5	5	10	10	5	5
Aplication development	5	5	10	5	5	5
Scalability	5	5	5	5	5	10
Management system	30	20	10	20	30	20
Compliance	10	10	10	10	10	10
Culture	10	10	5	20	15	10
Leadership	10	20	10	10	10	10
Competences	10	10	10	10	5	5
Σ	100	100	100	100	100	100

According assess ed goals is used Technique Nominal Group (TNG) for defining key variables for achieving proposed goals of Quality 4.0 (step 3). The list of eleven variables are weighted and it is base for defining the base model for transition of Quality 4.0 into Quality 5.0 (Figure 4).

**Figure 4.** Base model for transition from Quality 4.0 to Quality 5.0

The variables are: (1) Industry 4.0 level, (2)

Quality 4.0 level, (3) broader then structure of leadership in model of Quality 4.0. and Quality 5.0 is broader with interconnections with envionment, and (4) intangible capital needed for transition and (5) Quality 5.0.

The metrix for variable SISL is presented in Table 2 with weights for assessing.

Using this metrix is calculated value of varriable v3 (SISL).

Variable v1 (Industry 4.0) is also assessed based on literature review presented in previos chapter. The metrix for assesment Industry 4.0 level is presented in Table 3 (Yang K., 2018).

**Table 2.** Metrics for (Sustainable, Intelligent and Spiritual Leadership)

Weight	Spiritual leadership	Intelligent leadership	Sustainable leadership	Average value
Enterprise				
Micro enterprise	20	10	5	13
Smal enterprise	20	20	15	17
Medium enterprise	30	30	30	30
Big enterprise	30	40	50	40
Σ	100	100	100	100

**Table 3.** Metrics for assessing level of Industry 4.0

Weight Enterprise	Cuber security	Smart logistics	Smart manufact. systems	Big data/ AI, IoT	Mass customization	System integration	Average value
Micro enterprise	5	10	15	10	10	15	12
Smal enterprise	10	15	20	20	20	25	20
Medium enterprise	20	30	30	30	30	35	30
Big enterprise	65	45	35	40	40	35	33
Σ	100	100	100	100	100	100	100

Variable v5 (Quality 5.0) is assessed based on Metrix presented in Table 4. Variable v4 (Intangibles needed for transition) is

assessed based on Metrix presented in Table 5.

**Table 4.** Metrix for assessing Quality 5.0

Weight Enterprise	Inclusion	Competi-tivity	Concern to customer	Government support	Strategy of digitalization	Quality of Life	Average value
Micro enterprise	10	15	15	25	10	10	15
Smal enterprise	15	20	25	25	20	15	20
Medium enterprise	20	25	30	25	30	20	25
Big enterprise	55	40	30	25	40	55	40
Σ	100	100	100	100	100	100	100

**Table 5.** Metrix for assessing v4 (Intangible capital needed for transition)

Weight Enterprise	Human capital	Cognitive capital	HR capital	Scientific capital	Social capital	Spiritual capital	Sustainable capital	Average value
Micro enterprise	5	10	15	20	10	10	5	10
Smal enterprise	10	15	20	20	25	25	20	20
Medium enterprise	20	25	30	20	30	30	30	30
Big enterprise	65	50	35	40	35	35	45	40
Σ	100	100	100	100	100	100	100	100

In step 5 (Figure 3) are calculated inputs data from sample, which will be explained in next chapter, made simulation using statistical methods, DEA and ANN methods. Outcome from this step are simulation results presented in next chapter.

On this way are related steps 6 and 7. At the end is proved realization of stated goals and eventually repeated some steps until achieving the common goal.

**4. Case study**

The case study is provided in Republic

Serbia on sample of 235 enterprises with higher level of smartnesses. For each enterprise the assessment on scale 1-10 gave quality manager, consultant, production manager, logistic manager. The final assessment is calculated as average value. In the data base are included average values of all assessed variables. Using simulation software SPSS v.21 is calculated average value for each variable and thits standard deviation (Table 6). In the step 5 is calculated also regression coefficients (Table 7).

**Table 6.** Descriptive statistics

Descriptive Statistics							
	N	Range	Minimum	Maximum	Mean	Std. Deviation	Variance
V1	235	3,79	1,66	5,45	3,6351	,86574	,750
V2	235	4,20	2,20	6,40	4,3771	1,01361	1,027
V3	235	4,66	1,85	6,51	4,3399	1,09214	1,193
V4	235	4,35	2,08	6,43	4,9531	,99759	,995
V5	235	3,97	2,39	6,36	4,1308	,94980	,902
Valid N (listwise)	235						

**Table 7.** Regression coefficients

Correlations						
	V1	V2	V3	V4	V5	
V1	1	,692	,573	,535	,367	
V2		1	,644	,676	,671	
V3			1	,622	,552	
V4				1	,726	
V5					1	

The correlation among v5 and other variables are between 0.367 until 0.726 what is very high values.

For predicting impact of independent variables v2, v3 and v4 on dependent variable v5 are presented model summary

for v1 (table 8), impact of v1 on v2 (table 9), impact of v3 on v4 (table 10), model summary for predictor v3, impact of v3 on v4 (table 11), and model summary for predictors v2, v3 and v4 (table 12). All impacts are positive effects. Impact of v3 (SSIL) is 0.050 and impact of v4 (Intangible

Capital) is 0.485. Aftor analysis is possible to recognise that impact of SSIL is relative low (because is not recognized by questionared persons) and impact of intangible Capital is mach higher (0.485) and it can be used as base for sucefull transition from Quality 4.0 to Quality 5.0.

In next phase is performed DEA (Data Envelope Analysis based on DEAP version

2.1). Efficiencies plotet on diagrams (figures 5, 6 and 7) pointed out that exists groups of assesment near optimal values. On this base view is possible to find optimal way for improving transition to Quality 5.0 (variable v5) in dependance of variables v2, v3 and v4. This prediction is based on existing state of level of variables in sample.

**Figure 5.** Impact V2 and V3 on V5

**Figure 6.** Impact V2 and V4 on V5

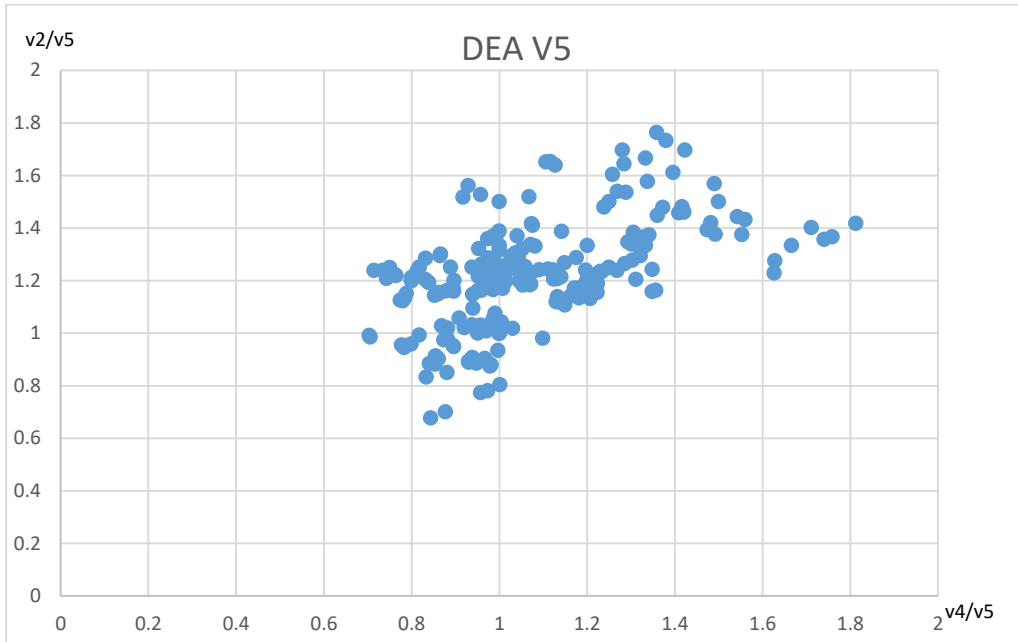

Figure 7. Impact V3 and V4 on V5

In purpose to predict level of Quality 5.0 in the future is used ANN (Artificial Neural Network) be using base model, key variables

and variation of their impact in the future (figures 8, 9, and 10).

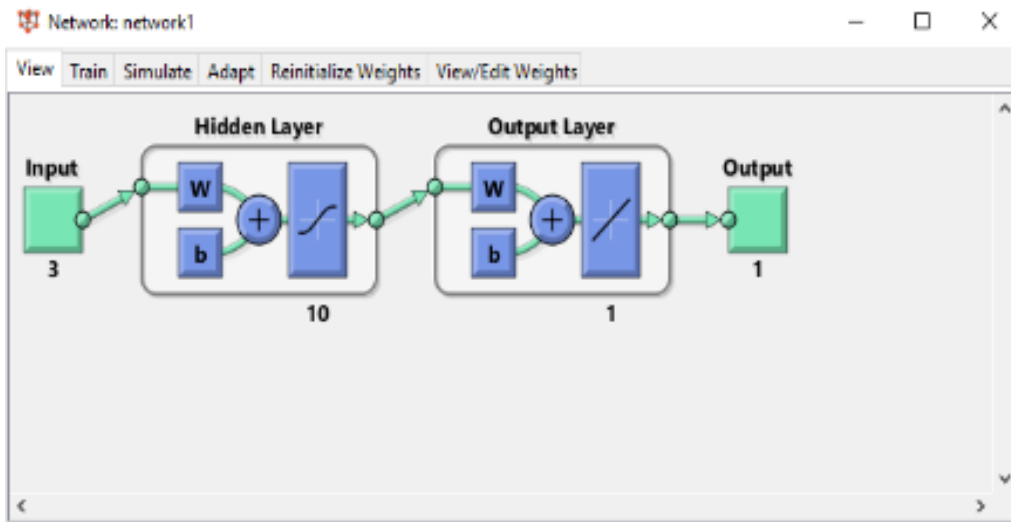

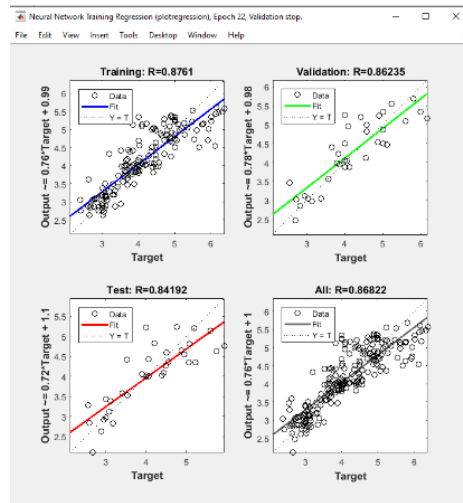

Figure 8. Layers in ANN model

**Figure 9.** Validation of ANN model

Based on five inputs and one output is defined structure of neural network (Figure 8) with ten hidden layer and one output layer. Using appropriate software is made training of neural network (Figure 9). Results of training of neural network proved high correlation between output and target value ( $R=0.8761$ ). On this way is proved that exists conformity among real and forecasting values (Figure 10).

Using this approach is conducted ANN

predictions which also pointed out that is prediction of value of Quality 5.0 is very high for all 235 cases in sample.

In next step is analyzed impact of independent variables  $v_1, v_2, v_3,$  and  $v_4,$  on dependent variable  $v_5$ . For purpose to demonstrate accuracy of ANN in Figures 10 are presented ANN predictions in comparison with real values for all cases in sample. Author pointed out that in all cases are very high conformity among them.

**Figure 10.** ANN prediction

## 5. Conclusion

A concept of Quality 4.0 is emerging in different aspects but is related with a lot of dilemmas and different approaches. On the other side according concept Society 5.0 author made one step more to develop concept at Quality 5.0. This attempt is investigated in Center for Quality (CQM) last in four years from theoretical and applicative approaches.

In the research presented in the article is used scientific approach from Quality Science (Arsovski S., 2017) and using it avoid „sciles and haribdes“ in this new research thema „Quality 4.0/5.0“.

The results of research proved attractive goals, i.e.:

1. Defined new concept of Sustainable, Intelligent and Spiritual Leadership (SISL),
2. Defined Model of Smart Transition (MST) from concept Quality 4.0 to Quality 5.0 and
3. Assessed impact of SISL, in the transition process.

For the research are used concepts of Grounded Theory, Reframing organizations and Process Modeling approaches. In purpose to confirm proposed model is organised research in 235 with relative higher level of digitalization and quality. For each variable is defined metrics and answers of correspondens. Quality manager were collected and formed Data Base for further application of statistical method using IBM Software SPSS v21, DEA (Data Envelope Analysis) and ANN (Artificial Neural Network).

Using ANN software are performed prediction of value v5 in all 235 enterprises. Impact of independent variables v2, v3 and v4 is calculated according statistical analysis presented in table 10, i.e.:

$$V5 = 0.379 + 0.291 \times v2 + 0.044 \times v3 + 0.462 \times v4$$

For improvent in next five years for 10 percent the new espected value of v5 will be:

$$V5 = 0.379 \times 0.291 \times 4.8 + 0.044 \times 4.9 + 0.462 \times 5.5 = 4.532$$

This value of v5 is higher for 0.393 of mean value (4.1308) calculated by software SPSS v.21. It is improvement of 8 percent.

Results of statistical analysis proved base model with relative high correlation among independent and dependent variable v5 (level of Quality 5.0). In period of collecting input data of SISL authors recognised that correspondent dont persons adopt and recognize structure of SISL, they in many cases missundstand it and as result the impact of SISL on v5 small. In next period author plan to educate quality managers about significance of SISL and tray to improve their spirituality, smart intelligence and sustainable aspects of leadership. All variables had positive impact on v5 and with their positive improvement as results we can expect higher v5 in future. Level of improvement depends on possibility to investments in Intargible Capital and social support. In this time it is not sufficient in Serbia, as transition state, with relative small financial capacity. The greatest impact on v5 has v4 (level of Intargible Capital). Authors expected it because all analysed enterprises had establish with generally high values of components of Intargible Capital.

Variables V1, V2, V3 and V4 have impact on other enablers of V5 and its ipact in total on V5is much higher. For estimtion of this impact is not sufficient linear model used for calculating by software SPSS. Author proposed for further research using non-linear model and broather model of V5 based on monitoring key enablers (a new variables in model) in purpose to estimate small improvement in each of them and its sinergy and total impact on Quality 5.0. It is so caled „Buterfly effects“.

Using DEA is analysed efficiency of impact of underdent variables on v5 (level of Quality 5.0). In all casses is calculate efficiency for each of 235 enterprises. Overal firm efficiency varied from 0.6 to 0.8, what is relative good results for the sample of 235 enterprises.

Through using ANN is also confirm that exist very good accuracy between real data of v5 and value of v5 calculate using ANN. This is base for conform the proposed methodology and impact of variables v1, v2, v3, and v4 on v5 (level of Quality 5.0) in the future.

This model is related with meny difficulties. The first, the assessing of SISL is conected with personal assessment without enough knowledge about Spirituality, Intelligent and Smart Leadership. On the other side knowledge related to Industry 4.0 are also relative on lower level and assessments were in some cases problematic. Next problem is

support of government which is different for different enterprises and also were different investment from own financial sources.

All of previos difficulties can override in next research in four areas, i.e.:

1. higher education of SISL and other human resources of enterprises,
2. higher sample and providing analysis for different type of industries,
3. Using methods of Artificial Intelligence and cooperation with foreign research,
4. Including other independent variables and making new hierarchical model appropriated for application of new simulation tools,
5. Developing the new international project related to enabling factors on Quality 4.0/5.0 and their impact on Society 5.0 as answer on Millenium goals of our civilization.

## GROUP DECISION-MAKING APPROACH FOR RANKING AND SELECTING MAINTENANCE TASKS FOR JOINT SCHEDULING WITH PRODUCTION ORDERS

**Abstract:** *Group decision-making has captured the attention of researchers for decades but due to its importance and complexity further explorations and studies, namely for its application in industrial engineering continue to be needed in the current digital age. In this paper, a group decision-making approach is put forward for evaluating and selecting maintenance tasks to enable joint maintenance and production management, by using a collaborative management system. The proposed approach includes a two-stage assessment method, which enables a set of decision makers to collaborate in ranking and selecting a set of maintenance tasks for being jointly scheduled with production orders. The group decision-making approach uses a dynamic multi-criteria decision model that aggregates information about historical, current and provisional data about maintenance tasks. The proposed collaborative approach is illustrated through an application example and further contextualized within the state of the art. This study permits to realize that collaborative management approaches, namely based on group decision making approach, enable conducting a dynamic, integrated, distributed, intelligent, predictive, time and condition based maintenance task management in real time, based on the fusion of past, present and future data, and that there is still a lack of contributions regarding the use of collaborative approaches in industrial management.*

**Keywords:** *Group decision making, dynamic, real time, integrated, distributed, time and condition based maintenance management*

### 1. Introduction

Group decision making (GDM) is a research topic that falls within collaboration, and collaborative management domain (Varela, Putnik, & Romero, 2022; Varela, et al., 2022a), and is of primer relevance in the

digitalization era, by promoting and enabling a sustainable development of companies (Varela, Putnik, & Romero, 2022, 2023; Varela, et al., 2022a,b, 2023).

The development of GDM approaches require the acquisition, processing and analysis of varying kind of data, which

---

Corresponding author: Leonilde Varela  
Email: [leonilde@dps.uminho.pt](mailto:leonilde@dps.uminho.pt)

typically is expressed through Key Performance Indicators (KPI), for being monitored and controlled by using appropriate dashboards and systems (Simonov, et al. 2018).

Over the last 20 years, the processing industries have invested heavily in automation and plant information systems such that the data is now accessible. As a result, this data should now be possible to put into productive usage. The challenge with raw data, no matter how accessible, is that it is just data, and data still requires a lot of work before it can be turned into knowledge. In most cases, the data needs to be validated, analysed and converted into a level of knowledge that is actionable, and this can still require a significant investment of time and resources.

Several kind of KPI have been frequently used to analyse companies' performance in a given context intending to reach certain organizational goals. Every companies' functional group defines its objectives and targets, and if the raw operational data can be converted in KPI for being processed and analysed, preferably in real-time a better monitoring and control, on the processed data can be reached and thus better decision making processes can occur.

Information monitoring, based on proper DSS is fundamental for obtaining maximum profit out of KPI through the use of suitable systems' data visualization interfaces, and which are currently being improved by using advanced and dynamic digital dashboards, namely through the use of power BI graphics that enable real time generated data to be analysed. Although, the real potential of a system data visualization interface relies on its interactive ability to quickly sort and display the consolidated performance metrics in order to highlight the top priority requirements and provide guidance on further actions required. This is performed through a combination of filtering, uncertainty filtering, normalization,

weighting, aggregation, ranking, and selection techniques, and put available through appropriate collaborative systems and platforms (Campanella, et al., 2012; Arrais-Castro, 2015a,b, 2018; Jassbi, et al, 2016; Varela, et al., 2018; Simonov, et al., 2018).

As mentioned by Knoen, & Oerlemans (2006), inter-organizational collaboration enables to unify disparate systems and solutions in order to achieve overall strategic and operational excellence. Therefore, intra and intercompany and manufacturing environments collaboration should be intensified, and this can be accomplished by putting into use appropriate group decision support approaches. Such kind of approaches will permit to fully integrate decision-making processes among diverse manufacturing plants and resources interactions, by using suitable platforms and systems offering effective support to carry out distributed and integrated management. Such unified workflow environments will thus promote and enable collaboration and support different decision making teams to work together with an understanding of their specific requirements in the context of a general view over an extended and/or virtual enterprise, which is of upmost importance in manufacturing and management, for instance in collective maintenance and production management.

Maintenance planning plays an important role in every service and manufacturing system, as it makes them more reliable and keeps them at an optimal operational level in order to provide high quality services and products. Additionally, the proportion of maintenance costs to the total production costs, which ranges from 15% to 70% according to the type of the manufacturing firm (McCall, 1956), makes maintenance planning a critical issue. Maintenance models can be broadly classified into two types: time-based and condition-based models (Rahmati, et al., 2018). Recently, the

joint optimization of production and maintenance plans has gained more attention. However, it has not been well studied compared to research on optimizing maintenance planning and production schedules independently (Pan, Liao, & Xi, 2012; Bajestani, Banjevic, & Beck, 2014; Fitouhi, et al., 2017). In addition to the above-mentioned classification of maintenance models, integrated maintenance and production scheduling models can also be classified into two types: integrated maintenance and production scheduling models with time-based maintenance activities; and integrated maintenance and production scheduling models with condition-based maintenance activities.

Maintenance operations can be classified into two main large groups: corrective maintenance (CM) and preventive maintenance (PM). CM corresponds to the actions carried out when the failure has already taken place, and PM is the action taken on a system while it is still operating. PM is carried out in order to keep the system at the desired level of operation, and several PM policies can be defined (Rahmati, Ahmadi, & Govindan, 2018; Sloan, & Shanthikumar, 2000; Taghipour, & Azimpoor, 2018), with the aim of determining when it is necessary to carry out PM operations on the machines according to different criteria used.

Besides maintenance planning, the maintenance and production scheduling is a critical decision process for the gainful management of any manufacturing system. While the first ensures reaching the production goals, besides the satisfaction of customer demands, the second ensures that manufacturing assets are available and in the proper condition to perform their required production tasks when needed. The two decision processes are interdependent since they share a clear common issue, the manufacturing assets that are used through production and restored by maintenance

actions.

Integrating production and maintenance scheduling will thus enable optimizing the joint production orders and maintenance task programming, while avoiding penalising drawbacks in companies (Ladj A, Varnier C, Tayeb FB-S. IPro-GA, 2016).

Although, according to the study conducted, it is possible to realize that there is still a gap in this research domain, as insufficient work has been put forward regarding joint maintenance and production management strategies and tools.

In order to provide a contribution in this focused domain, in this paper, a group decision-making (GDM) approach for supporting maintenance tasks assessment and selection is presented, for enabling further joint maintenance tasks and production orders scheduling, to reduce the lack of research that still prevails in this scientific domain. The proposed GDM approach is based on a Dynamic Multi-criteria Decision Model (DMCDM) (Varela, et al., 2018), implemented through a two-stage maintenance tasks processing (2SMTP) methodology, which is put available through a Collaborative Management System (CMS) that does further permit the integrated maintenance tasks and production orders scheduling.

To properly expose the developed work, this paper follows with a resumed literature review about DSS, MCDM and GDM, along with a general overview about approaches and systems for supporting maintenance and industrial operations management, in section 2. Next, the developed collaborative management system for joint maintenance tasks and production orders processing, along with the underlying group decision-making approach, and the proposed two-stage maintenance tasks assessment and selection method is briefly described, in section 3, and being further illustrated through and industrial example of

application, in section 4. Follows, a final discussion and contextualization of this work within the state of the art, in section 5, and the main conclusion and proposed future work in section 6.

## 2. Literature review

In this section, a general overview about decision support methods and systems, along with group decision-making approaches is briefly presented next, in subsection 2.1, followed by a summarized description of maintenance and industrial operations management approaches and decision support systems, in subsection 2.2.

### 2.1. Decision making methods and systems for group decision-making support

A Decision Support System (DSS) can be explained as an interactive computer-based system, which can be helpful for decision makers to use quantitative models and data for solving complex problems (Bhatt & Zaveri, 2002; Lee & Huh, 2006). A DSS enables supporting more or less complex decision processes by using different kind of middleware and technology, and tools (Sprague & Carlson, 1982; Zarate, 1991; Vieira, et al., 2018; Vafaei, et al. 2019). Keenan (2016) referred that DSS have been developed since 1970s, and since then continued growing and improving, based on new technologies, namely about databases and visual interfaces applied for properly supporting decision-making processes. DSS mostly involve Management Science and Operations Research fields. DSS and management strategies have thus a meaningful relationship in manufacturing environments for reaching well-suited decisions (Brannback, 1994).

During recent decades, DSS have been developed in different contexts, and some contributions are summarized next.

Group Decision Support Systems (GDSS)

and Executive Information Systems, which was changed to the Enterprise Information Systems (EIS), introduced to support DSS tools are becoming much improved and more effective. GDSS currently provides many useful options, including brainstorming, idea assessment and some other facilities for enabling communication in more or less complex problem solving scenarios (Costa et al. 2003; Limayem & Banerjee, 2006; Varela, et al., 2021), along with other kind of the so-called Integrated Decision Support System (IDSS) that enable improving the effectiveness of classical DSS by combining them (Liu et al. 2010).

More recently, DSS has applied in integrated models with Multiple Attribute Decision Making (MADM) and Multiple Objective Decision Making (MODM) in general framework of Multiple Criteria Decision Making (MCDM) for endowing a better process and environment in decision support (Jaramillo et al. 2005; Qureshi et al. 2017). Bakshi et al. (2015) mentioned that when there is uncertainty in decision-making processes the MCDM models will become more complicated thus requiring appropriate Multi-Criteria Decision Support Systems to present appropriate solutions in practice. The authors mention a new decision support system established based on models, survey (literature review) and human experts interacting through a proposed framework. The main issue of their research was selecting the main criteria in MCDM models. Some other studies applied this kind of approaches in practice, and some are resumed next, to mention a few.

Taha & Rostam (2012) applied a hybrid fuzzy AHP-PROMETHEE as main part of a decision support system for machine tool selection in flexible manufacturing cell. They mentioned that their research shows that MCDM methods can be a useful part of a DSS and that their vision would be helpful in decision making in solving complex cases.

Razmak&Aouni (2015) reviewed research related to MCDA and DSS and found out more than 100 research articles for analysis. They categorized the articles into 9 different sections, regarding their application fields. These 9 sections were: Production and Supply Chain Management; Education; Human Resource Management; Finance and Investments; Real state and Constructions; Environmental aspects; Medical aspects; Electronic business and electronic commerce, and Multimedia.

Leyva Lopez et al. (2016) proposed a model and system for supporting group decision-making based on a MCDM approach. The authors state that their approach was structured based on ELECTRE method and designed completely based on the web to turn the underlying process more reachable and easier applicable in practice. Their proposed GDSS enable to put forward some advices for decision makers in order to help them manage their priorities and preferences to allow proper decision rules with some degree of consistency and consensus.

In other works, namely in (Arrais-Castro, et al., 2018; Simonov, et al., 2018; Varela, et al., 2018), DSS models were proposed by using different kind of approaches, in different application contexts. According to the examples provided, it is possible to realize that DSS and approaches are applied in many different context and manufacturing and management environments, thus there is still need for new contributions to increase its full practical capability and usability, for instance, in the industrial context. Furthermore, decision making with uncertainty treatment and future or prospected data processing, needs integrated and advanced DSS models and systems to continue being developed to decrease ambiguity and vagueness of knowledge about forecasted data, which has become, especially currently, in the digital age, more urgent and necessary, for putting into practical

use in manufacturing management (Putnik, et al., 2021).

## **2.2. Approaches and systems for supporting maintenance and industrial operations management**

Maintenance is a crucial activity in industry, with a significant impact on costs and reliability, being immensely influential on a company's ability to be innovative, while permitting costs reduction and global benefits, namely increased quality and general performance.

In the scope of maintenance management, any unplanned downtime of machinery equipment or devices does usually degrade or harm a company's core business, potentially resulting in significant penalties and unmeasurable reputation loss. According to some studies, operation and maintenance costs can range from 15% to 70% of total production cost in some companies (Bevilacqua, & Braglia, 2000; Gong, & Qiao, 2014). Therefore, it is critical for companies to develop a well-implemented and efficient maintenance strategy to prevent unexpected drawbacks, and improve overall reliability, while reduce manufacturing systems' operating and maintenance costs.

The evolution of modern techniques, namely with the emergence of the Internet of things (IoT), along with varying kind of sensing technology, and new or improved artificial intelligence approaches and tools, among others, stimulates a transition of maintenance strategies from Reactive Maintenance (RM) to Preventive Maintenance (PM), and to Predictive Maintenance (PdM) (Jimenez, et al., 2020). RM is only executed to restore the operating state of the equipment after failure occurs, and thus tends to cause serious unproductive times, while frequently resulting in high response and repairation costs. PM is carried out according to a planned schedule based on time or process iterations to prevent breakdown, and thus

may perform unnecessary maintenance, typically resulting in high prevention costs. In order to achieve the best trade-off between the RM and PM, the PdM can be performed, based on some online assessment of the condition of manufacturing assets, and thus reach timely interventions before failure occurs, while preventing from high maintenance frequency, unplanned RM, and the incurrance in increased costs associated to frequent PM.

Asset management deals with the optimization of manufacturing assets use for reducing costs. An asset management system manages the assets over the whole life cycle, especially their reliability and efficiency. It is also responsible to optimize utilization and cost-effective maintenance of the assets. Moreover, it generates and provides information regarding the so-called “asset health” development and prognosis to support decision making of the enterprises’ production management (Namur, 2009). Using the “asset health” information to generate an optimal production plan is a viable solution to better integrate a maintenance and a production planning system to increase the overall performance (e.g. in terms of costs) of manufacturing operations. Although some work was already carried out in this sense, industry is still lacking of appropriate and effective systems for supporting advanced maintenance and production management (Zhai, Gehring, & Reinhart, 2021).

Biondi and Harjunoski (2017) proposed a joint scheduling approach for the production and maintenance of process plants that explicitly keeps track of the assets life cycle. The scheduling system includes a simple model of the asset wear that can be based on the concept of residual useful life (RUL) or of probability of failure. The authors state that the asset monitoring system is responsible of providing two types of information to the scheduling system: on the one hand, an estimation of the parameters

describing the wear caused by the production on the asset. On the other hand, if an extraordinary condition of the asset is detected, it is responsible to update a current RUL in the asset wear model of the scheduling system. Assets health information, along with the production orders, is managed by the scheduling system that takes care of the sequencing and timing of production tasks on the plant and triggers a maintenance action on the assets whenever this is required. According to the authors, their proposed method makes an effective use of factory units’ health information to generate a feasible plan for joint production and maintenance planning (Biondi, & Harjunoski, 2017).

Based on (Staufen, 2018), PM has not been properly explored in industry. A survey in 2020 shows that PM continues being a hot topic, for example to determine the best point in time to do maintenance tasks (Zhai, et al., 2020).

Two types of flexible PM strategies, i.e., time-based PM (TBPM) and condition-based PM (CBPM), are commonly analysed and applied (Wang, Yan, & Zhang, 2021). According to these authors, the application of TBPM is straightforward and relative ease of implementation, however, TBPM may lead to under-or over-maintenance due to inaccurate estimate of the stability of production systems. In contrast, CBPM is of more complexity, which continuously monitors and analyses the machine status to determine the implementation of the maintenance activity. The authors state that despite the complexity of computational requirement and uneven maintenance cycles, CBPM strategy can reduce the maintenance frequency to a minimum necessary level, thus improve a global production system’s productivity level.

Some examples of application of TBPM in diverse kind of production scenarios, integrating different production scheduling strategies, are presented in (Chen, 2000;

Chen, et al., 2006; Mosheiov and Sarig, 2009; Yang, Ma, Xu and Yang, 2011), while CBPM has also been focused by several researchers, for instance in (Zandieh, Khatami and Rahmati, 2017; Rahmati, Ahmadi and Govindan, 2018; Sloan and Shanthikumar, 2000; and Ghaleb, Taghipour, Sharifi and Zolfagharinia, 2020), just to mention a few.

Prognostics and health management (PHM) is a relatively young engineering discipline that aims to enable “real-time health assessment of a system under its actual operating conditions as well as the prediction of its future state based on up-to-date information” (Kim N-H, An D, Choi J-H, 2017), with PdM being the underlying maintenance strategy that uses prognostics results of PHM.

The authors of (Li N, Gebrael N, Lei Y, Bian, 2019) state that varying operational conditions have two major effects on system degradation: Firstly, varying operational conditions influence the speed of degradation. Secondly, they lead to sudden signal changes and change points, which result in high variance of raw sensor readings. Thus, varying operational conditions pose an obstacle to prognostics (Zhang, et al., 2020) and are considered to be a focal point for modern PdM modelling (Aydemir, Acar, 2018).

According to (Assaf, Scarf, & Iung, 2019), prognostics incorporates three tasks: ‘State estimation’ (estimate the current health or degradation state of the system based on historical data), ‘State prediction’ (predict the health or degradation state for future periods based on historical data), ‘EoL’ (‘End of Life’) or ‘RUL prediction’: Determine the RUL before failure or before exceeding the failure threshold for some identified degradation behaviour. The author highlights that RUL can refer to actual failure or remaining time until certain quality requirements of a product cannot be met.

Databased RUL prediction can be

formulated as a supervised (Aggarwal, et al., 2018) or a semi-supervised machine learning (ML) problem (Yoon, et al., 2017). According to these authors, the high amount of required failure data to derive RUL labels for supervised prediction models is often not available in industrial practice.

Health prognostics approaches in PHM are commonly classified into physics-based, knowledge-based and data-driven approaches (Bektas, Marshall, & Jones, 2019). Physics-based models describe the phenomena of failure and degradation as physical or mathematical “white box”-model. Although physics-based models can achieve high accuracy, their development is usually costly (Bektas, Marshall, & Jones, 2019). Knowledge-based models collect identified degradation behaviors and failure events in a historic database and assess the similarity of a currently observed system state with the entries of a knowledge base (Sikorska, et al., 2011). Data-based approaches make use of the system condition monitoring (CM) data to derive transparency of the system health state and predict the RUL (Song, et al., 2018; Jia, et al., 2018; Wang, et al., 2017), further enabling to assess the uncertainty of the prediction (Benker, et al., 2020). Databased methods encourage the use of highly adaptable ML, including deep learning (DL) algorithms (Zhang, et al., 2018), in scenarios where large amounts of condition monitoring data are available and the system operation is subject to variations, partially unknown conditions or a variety of failure modes.

For an overview of knowledge-based approaches, as well as advantages and limitations of data- and knowledge-based approaches, the reader is referred to (Ran, et al., 2019), where a survey of predictive maintenancesystems purposes and approaches is presented. Next, some additional work is briefly referred.

The authors in (Malhotra, et al., 2016) propose an approach for combined health

indicator (HI) estimation and RUL prediction. The publications by (Wang, 2010; Wang, et al., 2008) are among the first research works to explicitly consider the effects of time-varying operating conditions on system degradation analysis.

Li et al. (2019) model a dynamic, operation-specific degradation rate as a state transition function based on Wiener process and time-scale transformations, which capture the effect of operating conditions on the degradation curve. A measurement function smoothens the jumps in the degradation signal at operation condition change points by mapping each condition to a condition-specific baseline. The approach proposed by the authors is evaluated on a simulated data set of bearings, which are subject to varying rotational speeds, as well as on a data set from an accelerated degradation experimental study of rolling element bearings.

Luo et al. (2019) propose a deep learning approach for health estimation and fault detection of CNC machine tools operating under time-varying conditions. In a first step, the authors use a DL model composed of stacked auto encoders (AE) and a feed forward neural network to extract impulse responses from vibrational CM data. The training and test data sets for the DL model are prepared manually by labelling whether randomly selected time windows contain an impulse response or not. In case of an impulse response, the vibration signal represents the reaction of the system to sudden forces and impacts during time-varying machining processes. After training, the DL model is used to automatically identify impulse responses in the CM data. Subsequently, the first four natural frequencies and the damping reactions of the machine tools are extracted from two different impulse responses representing two different working conditions. The authors find that the natural frequencies barely change with varying operational conditions

and thus are a robust feature for HI construction. The HI is computed as the cosine similarity in the space of extracted dynamic features comparing current observations with an initial vector representing the normal state. According to the authors, since the HI is based on operation-condition invariant features, the HI is robust to different working conditions. However, the approach is not capable of performing an operation-specific prediction of system health for future loads. In contrast to most other research, the approach was evaluated on a real industrial data set, composed of vibration signals from 288 days of industrial operation.

Michau& Fink (2019) propose an unsupervised approach for system monitoring in a setting where a fleet of similar safety-critical systems is to be monitored over time. The training data for a specific system instance is enhanced by CM data from other instances of the fleet to enable CM early in a system's operational life. The authors use a variational autoencoder (VAE) architecture to model a shared latent space for the fleet, which is trained in an adversarial manner. A new loss function is designed to preserve instance-specific behaviours in the shared latent space. The health prediction is framed as a one-class classification, which aims at predicting whether the CM data is faulty or healthy. The method is evaluated using a real data set from a fleet of 112 power plants operated in different geographical locations and under different operational conditions. The authors refer that their results show that the shared latent representation and feature alignment yield an efficient and unsupervised feature representation in a setting of complex systems subject to varying conditions, which is useful for downstream PHM modelling.

The integrated optimization of production scheduling and machine maintenance has been known as a complex combinatorial

optimization problem, in which heuristic or meta-heuristic approaches are commonly employed aiming to find some satisfied solutions in short time. With the advent of artificial intelligence and machine and deep learning, the application of scheduling rules-based reinforcement learning (RL) to the field of scheduling has become possible (Wang, & Usher, 2005). However, little empirical research concerning the application of RL to integrated decision making of production scheduling and machine maintenance has been conducted (S. Zhai, B. Gehring, G. Reinhart, 2021).

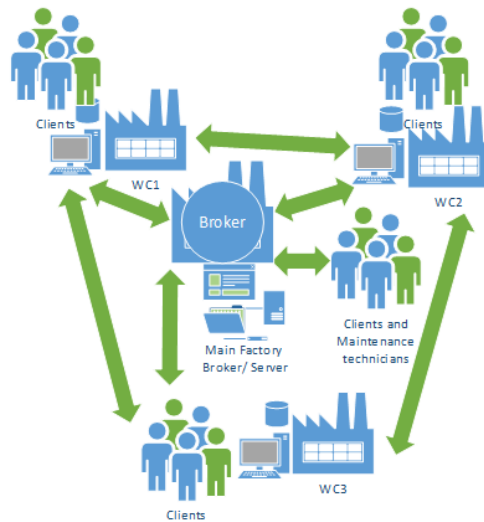

In (S. Zhai, B. Gehring, G. Reinhart, 2021) a machine degradation modelling under varying operational conditions, enabling subsequent integrated scheduling of maintenance and production (“PdM-integrated production scheduling”: PdM-IPS) is introduced. The underlying model is a conditional variational autoencoder (CVAE) that is used for calculating and quantifying the change of the machine health condition after producing specific product sequences.

The gap that continues existing regarding contributions of integrated maintenance and

production management approaches and systems motivated this work, in order to contribute to this scientific domain, and the proposed collaborative management system, based on a group decision-making approach is briefly described and illustrated in the next sections.

### 3. Collaborative management system based on a group decision making approach

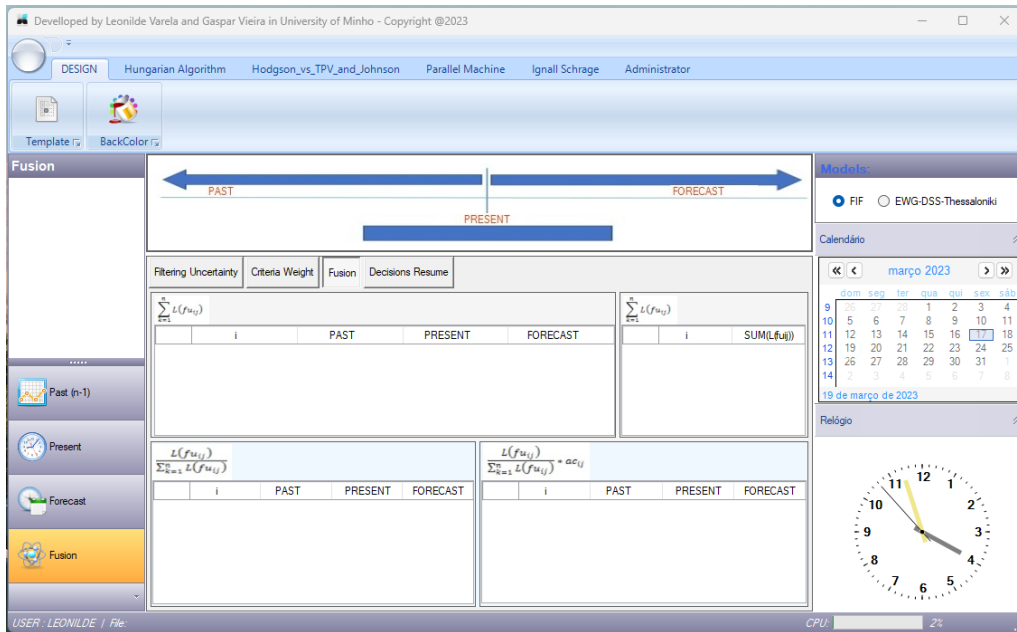

Collaborative management is of utmost importance in the current digital age, enabling and promoting a sustainable development of companies (Varela, Putnik, & Romero, 2022, 2023; Varela, et al., 2022a,b, 2023). In this paper, a group decision-making architecture is proposed to enable collaborative management, and Fig 1 shows an example of its application in an industrial company that includes three work centres (WC1, WC2, and WC3), which interact with each other and with the main company’s factory, through its underlying brokering service, besides communicating with clients, and maintenance technicians.

**Figure 1.** Group decision-making architecture

A collaborative management system (CMS) underlying the proposed group decision making architecture was developed to enable intra and inter factories and/ or work centres collaboration for jointly reaching integrated maintenance tasks and production operations

scheduling, and an interface of the CMS is shown in the Figure 2, about an interface for processing a data fusion function of the DMCDM used in this work that will be further explained through an application example.

**Figure 2.** Title (Times New Roman, 10pt, align Center, single spacing)

This CMS enables a wide range of diverse kind of other management functions in industrial management, namely underlying the proposed GDM approach, which is carried out by using a maintenance tasks processing methodology with three phases, based on a two-stage assessment method, which makes use of a DMCDM, as expressed

in the Figure 3.

The two-stage assessment method based on DMCDM was used in an industrial company, in the scope of a research project to enable the joint processing of maintenance and production orders information, and a case study is briefly described next.

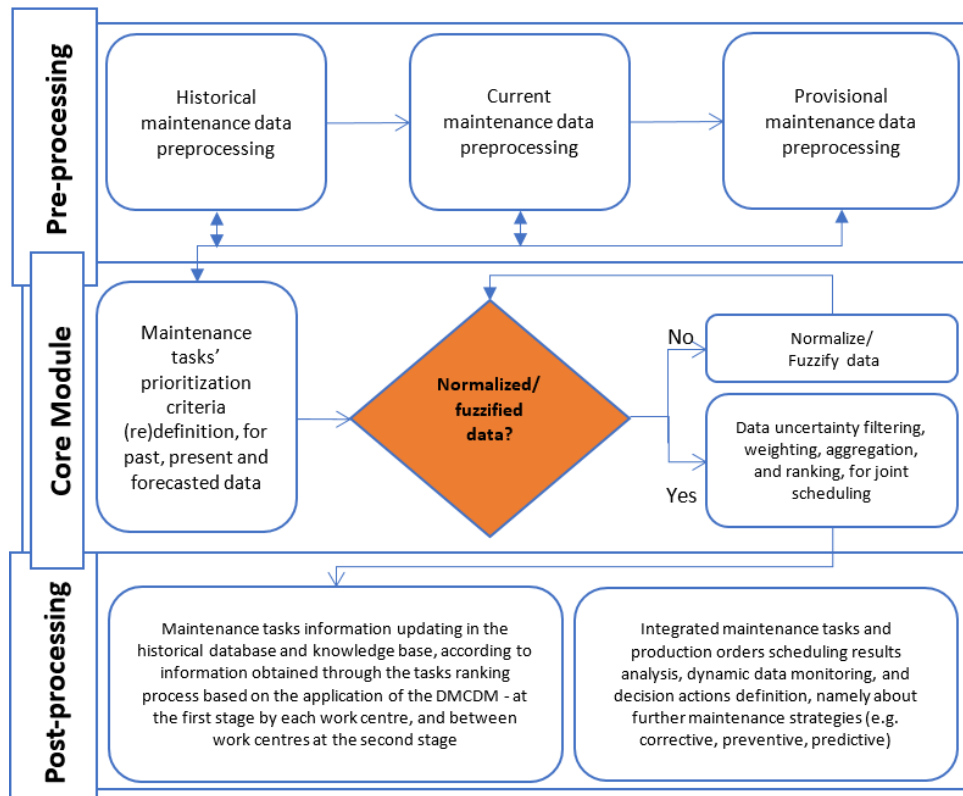

Figure 3. Title (Times New Roman, 10pt, align Center, single spacing)

## 4. Application example

### 4.1. Maintenance tasks assessment methodology based on a DMCDM

The maintenance tasks assessment methodology used in this work uses a DMCDM (Jassbi et al., 2013; Varela, Arrais-Castro, & Ribeiro, 2018), by including two stages, for intra and inter work centres tasks evaluation and selection.

**1st Stage) Intra work centres evaluation:** Includes 6 steps, for normalizing/ fuzzifying, weighting, uncertainty filtering, and data aggregation or fusion, for ranking and selecting the maintenance tasks (Varela, Arrais-Castro, & Ribeiro, 2018).

**Step 1) Data acquisition and matrices construction:** First, the definition of the evaluation criteria for processing the data about 3 moments: past, present and future, have to be defined, and Figs. 4 to 6 show an example for the company's WC1, by using different kinds of criteria, about: maintenance cost (MC), Lack of Production Quality (LPQ), Overall Equipment Effectiveness (OEE), Lack of Safety Indicator (LSI), Mean Time Between Failures (MTBF), Mean Time To Repair (MTTR), and Downtime (DT), for processing past and future maintenance tasks' data; and MC, along with Service Time (ST), and Lead Time (LT), for processing current maintenance tasks' data, which were applied for ranking a set of 6 maintenance tasks (M1\_1 to M1\_6) of WC1. The current or present data is acquired, in

real time from the shop floor, by using appropriate communication means and

devices (Vieira, et al., 2018; Varela, et al., 2021).

Maint. Task	Maint. Cost MC	Lack of Production Quality LPQ	Overall Equipment Effectiveness (100%) OEE	Lack of Safety Indicator LSI	Mean Time Between Failures MTBF	Mean Time To Repair MTRR	Downtime DT
MT1_1	630,00	28%	88	18%	28000	2	5
MT1_2	398,50	33%	79	14%	17500	4	4
MT1_3	400,00	17%	90	11%	18900	3	3
MT1_4	730,00	20%	85	13%	22400	2	3
MT1_5	490,00	15%	83	15%	15600	5	5
MT1_6	330,00	12%	92	12%	20580	1	4

Figure 4. Past data matrix

MT1_5	395,00	73%	20	80%	9	14000	5
MT1_6	340,00	84%	18	90%	4	11000	4

Figure 6. Future data matrix

The future data can be obtained by applying some forecasting method, namely by using some machine learning approach (Putnik, et al. 2021) or be based on known real or estimated data. Prediction may also be performed using expert judgment or quantitative methods (forecasting), such as moving linear averages, quadratic averages, and other techniques.

**Step 2) Normalization/ fuzzification**

In the second step a normalization/ fuzzification process underlying the DMCDM (Varela, Arrais-Castro, & Ribeiro, 2018) was performed (Fig. 7), to process imprecision by using fuzzy logic for criterion evaluation. To guarantee that values are numerical and comparable simple triangular membership functions were used to represent the acceptable criterion values,

as all expected criteria fit in the “lower is better” and “higher is better” categories (Varela and Ribeiro, 2003). This process is essential to enable values aggregation, and the simplest method consists on dividing a value by the maximum existing one in the set (when high values are favourable to the decision) or by the minimum (when low values are favourable, such as a cost) (Jassbi et al., 2014).

MC			
	x	u(x)	
1,1	630,00	0,250	
2,1	398,50	0,829	
3,1	400,00	0,825	
4,1	730,00	0,000	
5,1	490,00	0,600	
6,1	330,00	1,000	
			730-330

bi	330
pi	400

**Figure 7.** Normalization and fuzzification example for the MC criterion

### Step 3) Uncertainty filtering

In order to filter uncertainty a method underlying the DMCDM referred in (Varela, Arrais-Castro, & Ribeiro, 2018) is used, which considers two parameters, accuracy and confidence to “filter” the membership function values. The accuracy parameter expresses deviations from nominal values and the confidence expresses the degree of trust on the data gathered.

The logic of this filtering process is that if we do not trust an input source (e.g. confidence on data is only 80%) then the initial value must decrease proportionally (e.g. a value 10 would be reduced to 8), Thus accommodating deviations in the value, for example +3 or -3 from a value of 10.

Let  $a_{ij}$  be the accuracy associated with criterion  $j$  for  $MT_i$ , representing a left or right deviation from the original value; when  $a_{ij}$  is zero it means we accept the gathered value without deviation errors.

The confidence,  $w_{cj}$ , is a percentage, as for

example, we trust with 90% the values for “Maintenance Cost, MC”.

Additionally,  $\lambda \in [0,1]$ , is a parameter that reflects the decision maker’s attitude. Values close to zero indicate an optimistic attitude; higher values indicate a pessimist attitude.

The accuracy rate, expressing the allowed deviation from the base values, is defined for each criterion, based on the associated data quality. The value also reflects the imprecision associated with the data gathering process. Based on the criteria and its associated confidence rates, the filtered imprecision values,  $\llbracket fu \rrbracket_{ij}$  (e.g.  $ac_{ij}$ ), were calculated, as illustrated next for the MC criterion.

Hence, the adjusted membership value is calculated using the following formula (Varela, Arrais-Castro, & Ribeiro, 2018):

$$f u_{ij} = w_{c_j} * (1 - \lambda * \max_{x \in [a,b]} \{ |\mu(x) - \mu(x_{ij})| \}) * \mu(x_{ij}) \tag{1}$$

Where  $[a,b]$  is the inaccuracy interval:

$$a = \begin{cases} \min(D), & \text{if } x_{ij} - a_{ij} \leq \min(D) \\ x_{ij} - a_{ij}, & \text{if } x_{ij} - a_{ij} > \min(D) \end{cases} \tag{2}$$

$$b = \begin{cases} x_{ij} + a_{ij}, & \text{if } x_{ij} + a_{ij} \leq \max(D) \\ \max(D), & \text{if } x_{ij} + a_{ij} > \max(D) \end{cases} \tag{3}$$

Using the function (1), along with (2) and (3), we are able to penalize input values, which display any of the two types of uncertainty, i.e. inaccuracies or lack of confidence on data, within an optimist or pessimist view from the decision maker.

MC

wc <sub>j</sub>	100%	λ <sub>j</sub>	1	(in)acuracy int.	0%	pi	400	
i, j	u(xij)	xij	a <sub>ij</sub>	a	u(a)	b	u(b)	a <sub>cij</sub>
1,1	0,250	630	0	630	0,250	630	0,250	0,250
2,1	0,829	399	0	399	0,829	399	0,829	0,829
3,1	0,825	400	0	400	0,825	400	0,825	0,825
4,1	0,000	730	0	730	0,000	730	0,000	0,000
5,1	0,600	490	0	490	0,600	490	0,600	0,600
6,1	1,000	330	0	330	1,000	330	1,000	1,000

Figure 8. Uncertainty filtering example for the MC criterion

**Step 4) Weighting**

The step 4 enables to allow different weights for different temporal stages or criterion. Here we will use linear weighting functions to express the relative importance of criteria. These functions allow penalizing or rewarding bad or good levels of criteria satisfaction, i.e., instead of assigning single weights, we represent them using a function that depends on criteria satisfaction (equation 4):

$$L(fu_{ij}) = \alpha * \frac{1+\beta fu_{ij}}{1+\beta}, 0 \leq \alpha, \beta \leq 1 \quad (4)$$

where  $\alpha$  defines the semantic importance of criteria ('1' – very important, ... '0' - ignored), and the  $\beta$  parameter defines the slope for the weighting function (a higher value or slope means a steeper function, thus a higher penalty, e.g. '1', and '0' – null penalization) to penalize, more or less, badly satisfied criteria. For example, if we assign to criterion Maintenance Cost, MC the values  $\alpha=1$  and  $\beta=0.67$ , we are defining this cost as a “very important” evaluation parameter with an average slope decrease. In this case, we want to reward the best quotes and penalize the bad ones (i.e. we want to reward lower costs).

j=1 (MC)

i, j	fu <sub>ij</sub>	alfa	beta	L(fu <sub>ij</sub> )
1,1	0,250	1	0,670	0,699
2,1	0,829	1	0,670	0,931
3,1	0,825	1	0,670	0,930
4,1	0,000	1	0,670	0,599
5,1	0,600	1	0,670	0,840
6,1	1,000	1	0,670	1,000

Figure 9. Weighting example for the MC criterion

**Step 5) Aggregation**

After the four previous steps, we have a weighted vector for each criterion. The step five is to determine the score (rating) for each time period, past, current and future, by using an approach that is illustrated for the past values about the MC criterion. The following results were obtained for historic information, using the data fusion equation 5:

$$r_i = \text{sum}(\frac{L(fu_{ij})}{\sum_{k=1}^n L(fu_{ij})} * fu_{ij}) \quad (5)$$

i	MC	OEE	DT	PQI	MTTR	MTBF	SI
1	0,037	0,083	0,026	0,142	0,000	0,020	0,177
2	0,145	0,111	0,166	0,041	0,074	0,057	0,062
3	0,170	0,022	0,013	0,000	0,072	0,043	0,000
4	0,000	0,040	0,056	0,032	0,041	0,022	0,000
5	0,100	0,011	0,067	0,061	0,107	0,088	0,167
6	0,220	0,000	0,000	0,014	0,055	0,000	0,073

i	r <sub>i</sub>	Maint. Task
1	0,485	MT1_1
2	0,656	MT1_2
3	0,320	MT1_3
4	0,191	MT1_4
5	0,601	MT1_5
6	0,362	MT1_6

Figure 10. Aggregation example for the MC criterion in the past data matrix.

**Step 6) Decision**

Once applying the steps underlying the DMCDM: normalization/ fuzzification, weighing, uncertainty filtering, and aggregation or data fusion to the past information of the WC1, it is possible to obtain the following rankings of the corresponding 6 maintenance tasks considered in this example:

Maint. Task	Score	Position
MT1_2	0,65644141	1
MT1_5	0,6009151	2
MT1_1	0,48491111	3
MT1_6	0,36222612	4
MT1_3	0,31985451	5
MT1_4	0,19085262	6

**Figure 11.** Decision matrices example for the MC criterion.

Next, we repeat the process underlying the DMCDM for future information, and in this case study the same criteria that have been used for past information evaluation were used for future data processing. Once having calculated the historical and prediction (future) scores for each alternative, we also

need to evaluate the present status (present data).

Evaluating the present or current data means to evaluate the proposals/ quotes that have been received and then fusion the respective information. For that purpose, the following criteria were used to evaluate present data: MC (Maintenance Cost), ST (Service Time), and LT (Lead Time), as previously shown.

Summarizing, the final ratings of the maintenance tasks regarding past, future and present data, for the WC1, along with the final ratings, after final data weighting and fusion, for the WC1 are the following, correspondingly:

<p>WC1 - past</p> <table border="1" style="width: 100%;"> <thead> <tr> <th>Maint. **Figure 12.** Past, future, present and final scores matrices examples for all the criteria in WC1.

After the application of the same procedure that has been used for processing the information related to WC1 to the other two work centres (WC2, and WC3), by accomplishing the same main 5 steps of the DMCDM, the following final maintenance tasks' rankings have been obtained for these WC2 and WC3.

Next, the two maintenance tasks, out of each WC, with the higher ratings shown next are selected for further processing in the 2nd stage of the maintenance data processing method.

It is important to notice that despite M1\_3 not having good rankings in terms of historical data evaluation, it benefits from the greater importance that has been given in WC1 to the present or current data.

WC2 – final scores

Maint. Task	Score	Position
MT2_2	0,5699688	1
MT2_6	0,5284007	2
MT2_5	0,4882188	3
MT2_4	0,3952934	4
MT2_3	0,3838716	5
MT2_1	0,3742694	6

WC3 – final scores

Maint. Task	Score	Position
MT3_1	0,6617229	1
MT3_2	0,5652877	2
MT3_5	0,4242146	3
MT3_3	0,4114283	4
MT3_6	0,3966577	5
MT3_4	0,3958268	6

Figure 13. Past, future, present and final scores matrices examples for all the criteria in WC1.

Although, regarding the MT1\_5, it reaches a higher rating than MT1\_6, besides being a little worse positioned in terms of present data ratings, and with considerably worse position regarding future data, as the past data has a higher impact in the final rating than the provisional of future data, which in this case this favours MT1\_5.

**2nd stage) Inter work centres evaluation**

In the 2ndstage, the DMCDN isrepeated for the best rankings obtained in the 1st stage. Thus, follows the application of the same approach to the six maintenance tasks from the 1st stage with a higher ranking to be further processed based on the application of the same DMCDM by the whole set of decision makers underlying the WC1, WC2, and WC3, to obtain the final list of the three maintenance tasks with higher priority for being jointly scheduled with the production

orders, by repeating the application of the same main 5 steps that were previously applied on each WC.

In this 2nd stage of the method, a higher importance has been given to the past data, followed by present and less importance to the future data, to obtain the final overall rankings.

Thus, the 3 maintenance tasks with better ratings - out of the set of the six maintenance tasks list including the two of each WC with a higher priority - that were reached for being jointly scheduled with the production orders are the following: MT2\_2 (being redefined as simply M2, the M3\_2, redefined as M3, and M1\_5, redefined as M1).

It is important to notice that eventually other criteria and importance could be defined for accomplishing this second stage of the decision method.

(a) Final scores of MTi from 1<sup>st</sup> stage

i	Score	Maint. Task
1	0,5652022	MT1_3
2	0,5343635	MT1_5
3	0,5699688	MT2_2
4	0,5284007	MT2_6
5	0,6617229	MT3_1
6	0,5652877	MT3_2

(b) Final rankings of MTi from 2<sup>nd</sup> stage

Maint. Task	Score	Position
MT2_2	0,6463834	1
MT3_2	0,5581164	2
MT1_5	0,4785514	3
MT3_1	0,4774147	4
MT2_6	0,4337532	5
MT1_3	0,1708652	6

Figure 14. (a)Aggregated final scores’ matrices about WC1, WC2, and WC2 from the application of the 1st stage and (b) the 2nd stage of the maintenance tasks assessment methodology.

### 4.2. Collaborative scheduling: joint selected maintenance tasks and production orders programming

The joint collaborative scheduling is performed next, based on the model presented in (Varela, et al., 2022b), to jointly program a current set of companies' production orders, along with the previously selected set of the three maintenance tasks with higher scores: MT2\_2 that will now be defined simply as M2, MT3\_2 as M3, and M1\_5 as M1, related to the workcentres WC1, WC2, and WC3, correspondingly, and alternative possible solutions are shown in the Figs 15 to 17 below.

production orders, along with the previously selected set of the three maintenance tasks with higher scores: MT2\_2 that will now be defined simply as M2, MT3\_2 as M3, and M1\_5 as M1, related to the workcentres WC1, WC2, and WC3, correspondingly, and alternative possible solutions are shown in the Figs 15 to 17 below.

**Figure 15.** Gantt chart about the best solution found for scenario 1 (about the minimization of the internal performance measure, makespan, Cmax) (adapted from, (Varela, et al., 2022b))

**Figure 16.** Gantt chart about the best solution found scenario 2 (about the minimization of external measures, tardy jobs, Nt, and maximum tardiness, Tmax) (adapted from, (Varela, et al., 2022b))

**Figure 17.** Gantt chart about the best solution found for scenario 3 (about the combined (50%-50%) minimization of both kind of measures, Cmax, and Nt) (adapted from, (Varela, et al., 2022b))

These Gantt charts express possible alternative solutions for jointly scheduling the maintenance tasks and a set of ten lots of

production orders (L1 to L10), based on the preference that is given by the decision making team regarding internal oriented

performance measures(makespan) (Fig. 15) or external oriented ones(tardiness and tardy tasks) (Fig. 16) or a combination of internal and external measures (makespan and tardy tasks) (Fig. 17). Thus, the developed CMS provides additional flexibility by enabling to choose the best suited application scenario, by using appropriate scheduling algorithms put available for processing the joints maintenance and production tasks, according to a given industrial context and management preferences or goals of the decision making team.

## 5. Final Discussion

According to a study conducted, and by analysing a set of twenty publications about maintenance and production management a resume of main contributions from the literature were analysed, considering a set of seven main dimensions underlying this study about: dynamic, integrated, real-time, distributed, and predictive management strategies (Varela, et al., 2023), along with time and condition based maintenance, as synthesized in the Table 1.

**Table 1.** Resume of main dimensions of literature contributions and proposed approach

Dimension	Dynamic	Integrated	Real time based	Distributed	Predictive	Time based	Condition based

The analysed publications listed in the Table 1 show that, on average, 3 to 4 of the dimensions proposed for carrying out the collaborative maintenance and production management are considered. Therefore, it is noticeable that this work is novel and that there is still a gap regarding this kind of contributions in the focused scientific and technological domain.

## 6. Conclusion

In this paper a group decision making (GDM) approach for maintenance tasks ranking and selection for being jointly scheduled with production orders was put forward. The proposed approach was implemented based on a two-stage assessment method, which makes use of a dynamic multi-criteria decision method (DMCDM). The DMCDM enables to merge and jointly process and analyse maintenance information regarding historical, current and provisional data, based on corresponding subsets of criteria, which are defined according to a group of decision makers that interact on its definition and application of the proposed underlying maintenance tasks processing methodology, which is accessible through a developed collaborative management system (CMS), accessible by a set of entities for enabling joint decision-making. The utilization of the proposed GDM approach was illustrated through an industrial example of application and it revealed to be promising in supporting joint maintenance and manufacturing orders processing, once permitting to rank and select a set of maintenance tasks with highest scores for being jointly scheduled with

production orders by using other functionalities included in the CMS. This is a novel contribution, as far as our knowledge, and based on the study conducted there are no similar contributions in the literature that enable a distributed and dynamic maintenance tasks assessment and selection, based on a DMCDM, for being further jointly programmed with production orders, through the CMS. Besides, the CMS includes other functionality, namely for predicting maintenance key performance indicators, which are considered through criteria included in the prognostic data processed using the DMCDM, such as mean time before failure. Thus, this works contributes to the maintenance and production orders management scientific domain, which continues lacking of contributions that enable collaborative decision-making, which is considered of utmost importance to promote a sustainable development of companies, and is supported by new technologies underlying the current digital age, being still necessary further developments and industrial applications to be explored.

**Acknowledgment:** This work was supported by national funds through the FCT - Fundação para a Ciência e Tecnologia through the R&D Units Project Scopes: UIDB/00319/2020, and EXPL/EME-SIS/1224/2021.

This project was also funded by national funds, through the FCT-Fundação para a Ciência e Tecnologia within the R&D Units Projects UIDB/05549/2020 and UIDP/05549/2020.

## **EMOI: AN INNOVATION MANAGEMENT MODEL PROPOSAL**

***Abstract:** In the last two centuries, mankind has developed an accelerated technology change process, since the first industrial revolution up to the present, so called by some, fourth industrial revolution. The innovation processes and activities have played a fundamental role in this evolution. In future decades innovation will continue playing central role in the way society faces challenges such as climate change, energy shortage or population growth. For organizations of any type, managing the innovations process is becoming essential, far from the idea that innovation is always based in brilliant, isolated good ideas. What we present in this paper is a model to manage innovation processes and activities inside organizations. Our EMOI (Excellence in the Management of Organizational Innovation) model proposes a series of steps to be followed and a catalog of useful tools to empower innovation processes. Competencies required in innovation management are also considered.*

***Keywords:** Innovation, Management, Innovation tools*

### **1. Introduction**

The concept of innovation is particularly important nowadays as it implies for many organizations a differential element of competitiveness. This has not always been the case. The term "innovative" has had a negative meaning since the first Greek philosophers (for whom it meant changes in the status quo, therefore, a malign or, at least, uncomfortable approach) until the late 19th and early 20th centuries (Castro and Fernández, 2013), when it is linked to "novelties in things" and not only in the social, political or economic order.

According to its usual interpretation, innovation would include the following five cases:

- The introduction into the market of a new good, that is, a good with

which consumers are not yet familiar, or of a new class of goods.

- The introduction of a new method of production, that is, a method not yet tried and tested in the branch of industry concerned, which needs to be based on a new scientific discovery.
- The opening of a new market in a country, whether the market already existed in another country or not.
- The conquest of a new source of supply of raw materials or semi-finished products, again regardless of whether this source already exists or is to be created anew.
- The implementation of a new structure in a market, such as the creation of a monopoly position.
- The following are some definitions provided by leading authors that we

consider important because of the ideas they incorporate:

- Process by which, from an idea, invention or recognition of a need, a useful product, technique or service is developed (S. Gee, 1981).
- Innovation is an idea transformed into something sold or used (Piatier, 1981).
- A set of activities, in a given time and place, that lead to the successful introduction of an idea in the market, for the first time, in the form of new or improved products. Management and organizational services or techniques (Pavón and Goodman, 1987).
- Innovation is the complex process of bringing ideas to the market in the form of new or improved products or services (Cotec, 1988).
- To innovate is to want to create value in a systematic way (Parra, 2002).
- To innovate is to create a new (or improved) product or process - or a combination of both - that differs significantly from previous products or processes and that has been made available to potential users (product) or put into use (process) (Oslo Manual, OECD/Eurostat 2018).

From the Center for Quality and Change Management of the Universitat Politecnica de Valencia (Polytechnic University of Valencia) (CQ/UPV) we have been working for more than 15 years in the field of innovation and we work mainly with the development of 2 conceptual axes about "what is innovation":

The first one talks about the personal attitude to innovate through observation, thinking and execution:

- "It is a unique sensation to see what no one has seen before and to understand what no one knew how

to explain before" (Friedman, 1990).

- "To innovate is to see what everyone else sees, to think what few others think, to do what no one else does..., obtaining a product, a service or a process that does not ruin your organization and that makes you money by commercializing or implementing it." (Montesinos et al., 2020).

The second deals with innovation as a process within an organization's management system that allows the transmission of knowledge in the form of added value:

- Research and Development is a process where resources are used to generate knowledge. Innovation (with a capital I) is not necessarily a consequence. It is a different process in which knowledge is used to generate ADDED VALUE (Nieto, 2010).

This point deserves special attention, both from the perspective of public government and University Management. The generation of knowledge (transformation of resources into stock of knowledge) requires a stable investment since obtaining specific results is neither immediate nor occurs as a natural, unforced consequence of the process. Knowledge generation produces results mostly if it is driven by KNOWLEDGE TRANSFER.

We understand knowledge transfer as the actions, structures and personnel dedicated to transform KNOWLEDGE (known, understood and applied) into ADDED VALUE for a THIRD PARTY.

Societies that do not generate knowledge have problems to be a reference in the generation of innovation. And, for these societies, without innovation there is a future imposed by those who do innovate.

**Figure 1.** Difference between innovation and research and development

From the perspective of the spaces where knowledge is generated, it is fundamental to understand that if there are no structures, personnel and/or budget to transfer knowledge, these institutions pass (or remain) in spaces of inconsequence.

### 1.1. Types of innovation

Just as there are countless definitions of the concept of innovation, there are also numerous criteria for classifying innovation. At CQ/UPV we basically work with 5 criteria:

- The area of application.
- The scope of the innovation.
- The knowledge bases on which it is based.
- The functions of the organization where it is applied.
- The organizational dimensions (hexagon for innovation).

According to the application area we consider: Product innovation; Service innovation; Innovation in the process; Innovation in the market; New functionalities of existing products; Innovation in raw materials; Innovation in marketing and distribution and Social innovation, among others

In this taxonomy we subordinate the product and the service to the process that supports it. Innovation occurs with a new product or with modifications to an existing product (additions, changes, simplifications, or improvements). The same happens with the service, with the process or with any of the other categories.

From another perspective, and depending on the scope of innovation, we can distinguish two ways of practicing innovation:

- Incremental innovation: progressive incorporation of improvements in existing products, services, processes (or combinations of the three) in order to improve performance or reduce costs. In this sense, incremental innovation and continuous improvement are very close, sometimes indistinguishable.
- Radical innovation: essential modification of the characteristics and benefits offered to stakeholders of a product or service that generates a new need, meets current needs or fulfills explicit or implicit expectations.

Researchers at CIRCLE (Centre for Innovation, Research and Competence in the Learning Economy, Lund University, Sweden) led by Professor Ashiem (Ashiem

et al 2005) propose to consider the origins of knowledge, the actors and resources involved, the necessary interrelation processes between environments and the consequences of innovation in order to classify it according to the basis and generation of the knowledge that sustains it. They identify three different knowledge bases to produce innovation: Analytical, Synthetic and Symbolic innovation.

Analytical knowledge is based on science and underpins innovations based on formal, deductive tools and processes. It is mostly shared in scientific publications or in licensing. Synthetic knowledge comes from the world of practice and engineering and is achieved by combinations of existing knowledge or improvements in its application. Symbolic knowledge, on the other hand, has its origin in the cultural and artistic practices of a collective to generate new representations and transmission of social, historical, popular or dystopian stories.

Also in this aspect, three major non-hierarchical areas are identified where the innovation activity has an impact: the business configuration, the engineering of what is offered and the customer interaction with the experiential elements of the organization.

The fifth criterion, the organizational dimensions (hexagon for innovation), will be exposed in the next epigraph, as it is especially relevant for our proposal of an Innovation Management Model.

## **2. The organizational dimensions (hexagon for innovation).**

At the Center for Quality and Change Management of the Polytechnic University of Valencia, since 2005 we have been reflecting on the different elements that explain the management of Innovation. As a research center of a public university, our

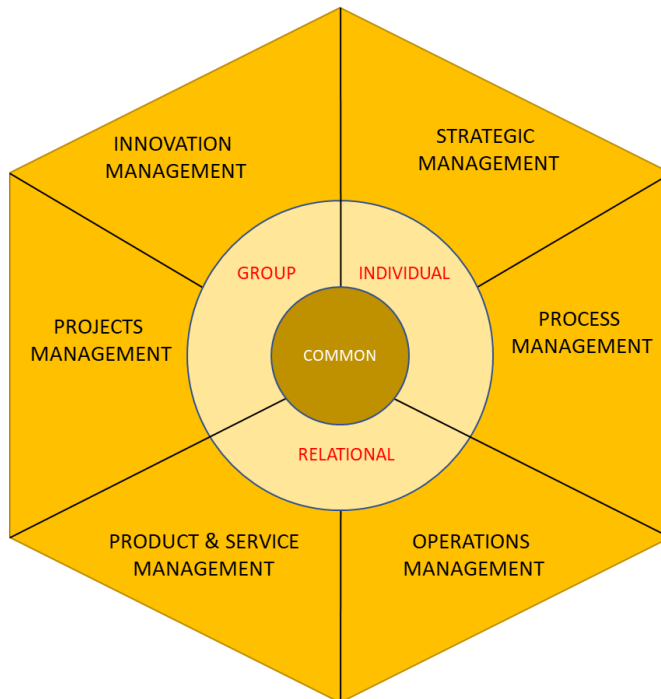

commitment to the generation of knowledge and with lifelong learning has led us to the development of a catalog of tools that allows us to identify not only what tools exist, but also in which dimensions of the organization they should be used.

A first conceptual step was to distinguish that there are some tools that lead to IMPROVEMENT and others that lead to INNOVATION. In both cases, we were able to identify competencies that managers and employees needed to have available to be able to act in one direction or another. The second stage was to distinguish in which dimensions of the organization it was possible to develop a specific innovation (or improvement) using our own tools.

Following this line of thought, we proposed three categories of competencies that would allow us to create a catalog of "competencies for innovation". Take into account that it is more relevant to identify required competencies, than to identify tools to be used: Tools are just the way of operatizing competencies.

In addition to a set of competencies common to all those involved in innovation processes, we identified three categories of competencies to consider. The first category corresponded to individual competencies, defining these competencies as those used individually by executives and managers to support the use of tools conducive to innovation. The second corresponds to group competencies, competencies that must be acquired to work effectively in a group to lead the use of tools to generate innovation. Finally, we identified relational competencies, those that must be acquired to drive innovation with support outside your own department, company or region.

In this process of constructing the model, we confirmed that the improvement-innovation distinction lost significance when we saw the scope of the dimensions and competencies.

**Figure 2.** Organizational dimensions and innovation competencies

In figure 2 we can see the six dimensions and the four categories of competencies. No relationship exists between the position in the figure) of the competencies categories and the organization dimensions: group and relational competencies can be required in each of the dimensions.

The hexagon allows us to represent six organizational dimensions in which innovation takes place and where it is possible, in turn, to identify specific tools that support the development of this innovation. The innovation action may be incremental or radical, based on analytical, synthetic or symbolic knowledge, or have as a consequence an application in any business function. Through this approach it is possible to make innovation appear as a matter of training, discipline and system. Constructive discourse based on the use of tools with the appropriate competencies opens up new spaces, forms and ways of generating

innovation without basing this process exclusively on inspiration.

The selection of innovation tools is outlined in Figure 3. The list of tools should be considered as an example, a list that is not complete nor exclusive.

The more than 40 tools identified by the Quality and Change Management Research Center of the UPV respond to a first need for a basic cataloguing of the methodologies on which organizations should work. Secondly, it is linked to the need to identify where the organization wants to place its investment and implementation efforts in innovation projects.

Innovation is not something ethereal or exclusively inspirational. It responds to specific drivers that force organizations to undergo situations of unstable dynamics and growth or, in the worst case, regression and collapse.

**Figure 3.** Innovation tools and the Hexagon of Innovation

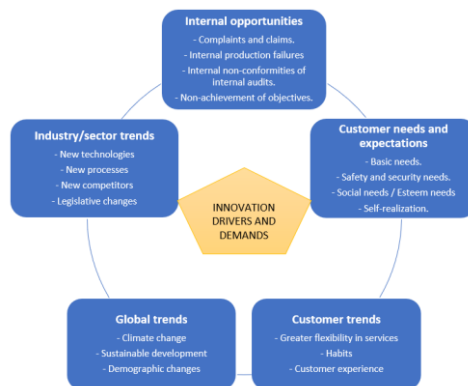

### 3. Innovation drivers and demands

Although much work has been done on the conceptualization of innovation, on tools, methodologies and competencies for excellence in innovation, what companies really need is a process that allows for the effective deployment of innovation at both the strategic and tactical or operational levels.

One of the most common mistakes of organizations in the deployment of their innovation process is to try to jump directly to the implementation of their innovative ideas, without properly defining the innovation challenge and for this we must pay attention to the input to the model. These are the trends, drivers and sources of innovation demands. These sources include the following five great categories:

Global trends  
Industry trends  
and expectations  
Internal Opportunities

Consumer trends  
Customer needs

**Figure 4.** Innovation drivers and demands

It is important to highlight the role of trends in innovation as a basis for defining innovation challenges. Trends allow us to understand change and innovation to act on it. In an innovation process, trends can help to define the user profile, inspire creativity, or future scenarios that help us to think about the evolution of products and services. Because of the relationship that exists around change, trends and innovation are completely connected, and they need each other to be useful.

This tendency analysis can be viewed as the first step of our Innovation Management Model, as it serves as source of innovative ideas and plans, and as input for the rest of the process.

#### 4. The Excellence in the Management of Organizational Innovation (EMOI) model

One of the most important criticisms of management systems defined according to the guidelines of international standards is that they are very generic, very bureaucratic and do not solve many practical problems that organizations usually encounter.

We have also seen that organizations, in many cases...

- Do not have at their disposal all the necessary knowledge to solve the demands that they usually encounter.
- In some cases, although they have the knowledge, they do not know how and when to use it.
- Do not know how to convert these demands into real challenges that really create added value to their products or services.

In order to solve some of these innovation management problems and to comply with the general principles of management excellence, we have developed the EMOI Model. This model is the result of the previous considerations presented in this

paper, and other that the limited space of a conference presentation makes impossible to include here.

It is an innovation management model that...

- Allows to manage in a structured and joint manner the necessary tools and methodologies to plan, deploy and measure innovation at all levels of the organization: strategic, tactical and operational, as well as the temporal sequence of use.

- It provides the necessary methodology to convert the demands and tendencies (social, consumer, internal to the organization...) into real challenges that really create added value to its products or services and that this is perceived as excellent by the stakeholders.

The EMOI Model is a model that manages tools, methodologies, activities and competencies and their application using the global 5F methodology. A methodology that defines which tools and methodologies to use, when and how. It is a model that allows to understand the innovation demands (E), to define innovation (D), to deploy it (D) and to evaluate its results (E).

The EMOI model is structured in 4 criteria (Figure 5):

- Criterion 1. Innovation demand profile.
- Criterion 2. Innovation value proposition.
- Criterion 3. Innovation spaces.
- Criterion 4. Innovation results.

Criterion 1 includes the tools and methodologies for analyzing the demands of stakeholders, the organization itself and its environment and answering questions like these: Who are the customers, and the stakeholders? What do I know about my customers? What are their expectations and needs? What is the organization currently doing to satisfy these needs? Strengths and weaknesses? Who are my competitors and what are they doing? Threats and opportunities?

Criterion 2 includes the tools and methodologies that make it possible to turn the voice of the innovation driver into the voice of the organization's innovation. This is the real heart of the EMOI model. During the deployment of this second criterion, it

will be possible to:

- Identify and define the innovation challenges.
- Identify the innovation space in which the challenge must be solved.

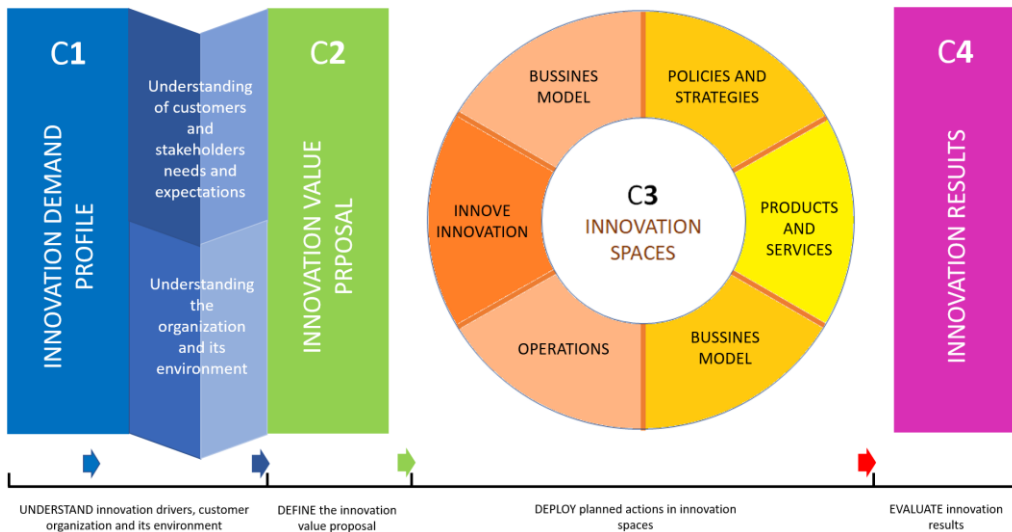

Figure 5. Criteria in the EMOI model

Criterion 3 includes the tools and methodologies that allow the different specialists of the organization to solve the innovation challenge. The different spaces where this innovation can be solved are shown in the Innovation Hexagon.

Finally, criterion 4 includes the tools and methodologies that allow us to answer the following questions: How do we measure the outcome of our innovation? How has the innovation solved the demands? Have we really increased the added value of our products and services and does the customer appreciate it? How are priorities for improvement decided in innovation management?

## 5. Global 5F implementation methodology

In the process of implementing the model, we can speak of 5 phases (the methodology for implementing the EMOI model is known as the 5F Global Methodology).

The methodology phases (Figure 6) cover the following activities:

- F1. The first phase includes the activities necessary to identify the sources of innovation demands.
- F2. The second phase includes the activities necessary to define the innovation demand profile that includes the result of the stakeholder analysis, the internal analysis of the organization itself and the analysis of the environment.

- F3. The third phase includes the activities to build the innovation value proposition, which includes the definition of the innovation strategies to solve the innovation demands and their prioritization, as well as the definition and planning of the innovation challenge that must be solved to satisfy the innovation demands.
- F4. This fourth phase includes the activities carried out by the specialists in each of the innovation spaces and that allow solving the innovation challenge.
- F5. The last phase includes the activities necessary to evaluate the results of the proposed innovation solution measured as the added value that the product or service offers to the different stakeholders.

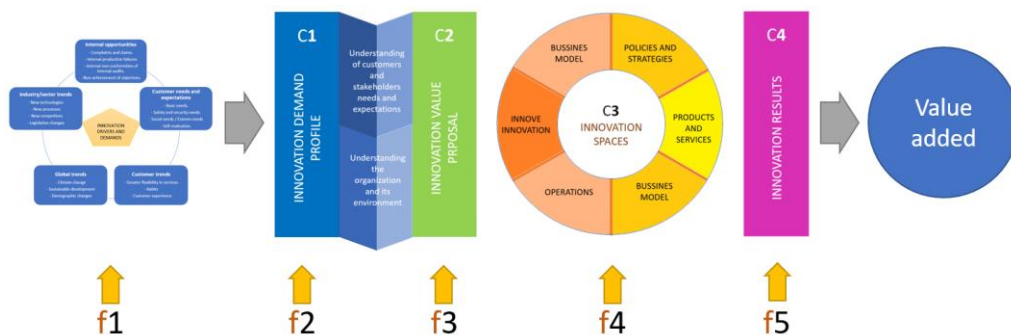

Figure 6. Global 5F methodology

## 6. Final comments and conclusions

EMOI model is not just a theoretical proposal. It has been tested in 130 companies, in different sectors and countries of Latin America (Perú, Colombia, Ecuador, Panamá, Uruguay, Paraguay, Argentina and Costa Rica), including industrial sector companies (chemical, food and agro, manufacture, ...) services (tourism, engineering, finances, assurances, ...) and public sector. Most of the are small and medium enterprises (SME), and their positive experience has shown us that the model, always subject of possible improvements, has helped these organizations to add value for their customers and to face future with better

perspectives. We are preparing a detailed, qualitative and quantitative analysis of the results achieved.

With this experience we are confident that EMOI model can help organizations to take the train of innovation, and continue being active in the markets and profitable. We have special interest in SME, because this is the greatest segment in many countries and, by its limited size, at the same time, they are the least likely to benefit from the use of complex management models with a strong tendency towards bureaucracy.

The model, as presented here, is complemented with a series of operative tools to facilitate the use of the Global 5F methodology, and guides and recommendations on how to use it to create value for customers.

## SYSTEM THINKING FOR BUSINESS MODEL INNOVATION

**Abstract:** *Management leaders can use systems thinking models to improve comprehension, creativity, and productivity. Systems thinking and business models or business model innovation (BMI) merge. As a complex management endeavour, the creation of BMI may require a significant contribution from the system thinking approach. We have evaluated the literature on systems theory, system thinking models, and business model innovation to demonstrate the promising role of system thinking models in BMI research and identify a system thinking strategy. The systems thinking methodology provides a framework for comprehending complexity, dynamic change, and advanced modelling technologies related to learning settings. This work introduces systems thinking methods, system dynamics (SD) and causal loop diagrams (CLD) to increase BMI complexity. The feedback that might solve issues with the system and innovation project boundaries, specifically the balancing loop, is one of the essential components of innovative management. A negative or balancing loop clarifies the system's behaviour, which empowers management to take creative and long-lasting action. A final CLD shows how to use this system thinking method for BMI. The research findings show that systems thinking concepts and techniques may offer the adaptability needed to better handle innovation, complexity, and uncertainty.*

**Keywords:** *systems thinking models, sustainable management, innovation management*

### 1. Introduction

Peter Senge presents the term systems thinking in his book *The Fifth Discipline* (1990). Systems thinking offers a different view of life and society; it identifies patterns and relationships among system elements and shows how to structure them more effectively. Systems Thinking is a discipline that enables:

- Observing a reality composed of dynamic systems.
- Building descriptive and simulation models.
- Improving the ability to acquire knowledge, i.e. learning.

- Developing intelligence.

Systems thinking, or thinking as a discipline, must be learned gradually through practice and continuous improvement. Peter Senge (Senge, 2006) presents systems thinking as an intuitive way without logical principles behind it.

Systems thinking, which has been developing over the last 60 years, is increasingly impacting science and its application in all areas of life. In short, systems thinking is the science of organising logic and integrating disciplines to understand the patterns and relationships of

---

Corresponding author: Tamara Papić  
Email: [tpapic@singidunum.ac.rs](mailto:tpapic@singidunum.ac.rs)

complex problems. Systems thinking is also known as principles of organisation or self-organisation theory, which includes 'systems' or 'holistic thinking. It is a science based on understanding the connections and relationships between seemingly isolated things (Haraldsson, 2004).

The logical structure of this discipline can be summarised in five basic rules that the systems thinker must always respect: to understand the world, one must be able to see the "wood from the forest"; one must develop the ability to "zoom in" on parts of the whole, from the whole system to the components; one must not limit one's observation to what appears to be constant, but "look for what changes" (Mella, 2008). Variables - "variations" and feedback loops - are what the systems thinker is interested in—systems thinking is more than just a chain of cause-and-effect relationships. By linking variables, we induce loops between all these variations to transform linear variations in the systemic interactions between variables. At the same time, when we observe the world, we must always define the boundaries of the system we are studying. The systems thinking model introduces two concepts: systems analysis (SA) and systems dynamics (SD)

**Figure 1.** Systems Thinking Model (Source: Haraldsson, 2004).

Systems Analysis (SA) is concerned with uncovering organisational structures in systems and generating insights into the organisation of causality. SA involves breaking down a problem and reassembling it to understand its components and feedback. Systems analysis involves group modelling, where an initial question, problem and mental model structure present the core of a causal loop diagram (CLD). This concept can unlock complex systems, managers and entrepreneurs for sustainability and innovation. The function of the DUP is to map the structure and feedback of a system to understand its feedback mechanisms. DUP serves to understand how behaviour manifests in a system so that strategies can be developed to work on or counteract certain behaviours. Every time we look at a problem, we ask questions, so we can constrain the system to the question asked, and the question becomes the system's boundary around the problem.

The term 'system dynamics' was first presented by Jay Forrester of MIT in the 1960s (Forrester, 1961). System dynamics is about re-creating an understanding of the system and its feedback. It aims to explore dynamic responses to changes within or outside the system. System dynamics create blueprints for interpreting the past and predicting the future. In addition, system dynamics deals with the mathematical representation of our mental models and is a second step after we have developed our mental model. System dynamics is also concerned with numerical analysis and understanding the uncertainty of the realistic representation in the developed mathematical model. All models, whether in the form of a written text, conceptual or mathematical, have an inherent structure of "systems thinking" built into them, as they are constructed according to certain thinking and logic. A model is successful when the thinking behind it is successfully transferred

from the model builder to the observer (Haraldsson & Sverdrup, 2003). A model that does not explain its principles is essentially useless. Therefore, using a common language to convey this understanding is crucial for communication between users and model builders.

Systems thinking provides a language for understanding complexity and dynamic change and offers sophisticated modelling technology and associated learning environments. For this paper, *innovation* is defined as the creation of new knowledge, services, products, and processes using new or existing scientific or technological knowledge that provides a degree of novelty.

Taylor (2017) also defined innovation as "a creative process in which new or improved ideas are successfully developed and applied to produce practical and valuable results". Nidumolu (2015) sees four stages of sustainable innovation-considering: alignment as an opportunity; creating value chains for sustainability; designing sustainable products and services; and developing new business models-describe variations of innovation that require different

levels of effort or change and have different levels of impact in the systems in which they operate.

The systems thinking model uses different tools to build holistic perspectives and practices for innovation and sustainable management.

## 2. Methodology

This paper explores different tools and how they can help develop sustainable management and innovative business models. Knowledge visualisation is a central concept with system dynamics (SD) and causal loop diagrams (CLD).

The visual representation of plans, processes, strategies, performance, and many other business entities is a fundamental underpinning of knowledge and practice in business management research (Eppler & Burkhard, 2004).

Figure 2 provides an overview of the most used diagrams in the knowledge visualisation process as ancillary tools in management decision-making.

**Figure 2.** The most used models (Source: Eppler & Burkhard, 2009)

Figure 3 illustrates the complexity of natural systems and the main contributing factors which can meet the requirements for dealing with complex management situations. Figure 3 shows how the above requirements can be met using systems thinking tools, leading to the desired results (Eppler & Burkhard, 2007).

System Dynamics (SD) has been established as a powerful approach to understanding, simulating, analysing, and predicting fluid, complex and dynamic business processes. One of the critical ways to translate human language into machine-readable language is the flowchart.

A causal loop diagram (CDU) is a system thinking tool that could be used to illustrate sustainable and innovative systems. CDUs consider sustainability and innovation as

focal points and expose new concepts that simplify complex webs of management, business, socio-economic and environmental subsystems (Haraldsson, 2004).

**Figure 3.** A framework of systems thinking tools to help achieve the desired outcomes contributing to sustainable management (Source: Ammirato & al., 2021).

### 3. The Complex Systems Modelling Paradigm

The complexity of individual systems is reflected in the ability to identify the best solution among many other solutions. The complexity dynamics increase over time depending on the interactions between subsystems or agents. Dynamic complexity increases as systems: (Serman, 2020)

- **Dynamic:** Heraclitus said, "Everything changes". Systemic changes occur at different times and sometimes influence each other. A star evolves for over a million years before burning through its hydrogen fuel and then exploding as a supernova in seconds. An evolving square can grow for years and then collapse in hours. After a long time,

what seems to be unchanging seems to change.

- **Highly interconnected:** System elements are highly interconnected, interacting with each other and with the natural world. Everything is connected to something else.
- **Feedback loop,** where feedback is the driving force: because the elements are so closely connected, our actions receive feedback about them. The dynamics arise from this feedback. Our decisions change the state of the world by causing changes in nature and by causing other changes, marking new situations that influence our future decisions.
- **Non-linear:** the effect is rarely proportional to the cause, and local developments often do not affect

distant areas. Non-linearity often arises from fundamental physical laws and several factors in decision-making - the pressure to achieve more increases motivation and effort, but only to the point where it becomes clear that the goal is unattainable.

- Historically dependent: Taking one path often precludes taking another and determines the end of the path (path dependency). Many actions are irreversible. A broken egg cannot be made whole (second law of thermodynamics). Stocks and flows (accumulation) and long-time lags often mean that action and inaction have different time constants.
- Self-organised: the dynamics of a system arise spontaneously from its internal structures. Frozen patterns, heartbeats, consistent real estate market targets and structures such as shells and markets arise spontaneously from feedback between factors and elements of the system. Often minor random disturbances, reinforced and shaped by feedback structures, form patterns in time and space and create path dependencies.
- Adaptability: The decision-making capabilities and rules of agents in complex systems change over time. Growth leads to selection and introduction; some agents while others disappear. Adaptation also occurs when people learn through experience, especially when they learn new ways to achieve their

goals in the face of obstacles. In any case, such learning is not always welcome.

- Intuitive control: In complex systems, causes and effects are distant in time and space, and we want to see the causes when the events we want to explain occur. High-impact policies are often not visible here. We are trying to draw attention to the symptoms of problems, not their causes.
- Political resilience: the complexity of the systems we are embedded in exceeds our capacity to understand them. The result: more apparent solutions to the problem fail or make the situation worse.
- Defined by substitution: Time lags in the feedback loop represent the long-term response of the system to an intervention, which is often different from the short-term response. High-impact policies often worsen situations in the short term and improve them in the long term. The opposite is true for low-impact policies, which often improve temporarily before the problem worsens.

Effective modelling involves constant iteration between experimenting and learning in the virtual world and experimenting and learning in the real world. Modelling is embedded in system dynamics. The figure below illustrates the embeddedness of modelling in the natural and virtual worlds by explaining the causal loop.

**Figure 4.** Explanation of the Causal Loop Diagram (CLD) (Source: Haraldsson, 2004)

When we use the DUP language, we use feedback to explain a process. We always start with an initial question: "What do I need to do to ensure he fills the water glass and understands how the water flows in the lesson?". Instead of seeing the action from the individual's point of view, where 'I am the doer and the centre of focus, we shift our perception, where 'I am' becomes part of the feedback process rather than separate from it. Suddenly we have turned our attention to the structure of the behaviour, and we can see that the structure causes the behaviour. The CLD follows the details, and the 'feedback' in the model can be read as a story. Since we want a certain amount of water in a glass, we start by turning the water tap (Senge, 1990);

The main objective is to understand how managers can use systems thinking to achieve the desired results.

#### 4. Results

The data sources in Figure 3 were used to generate CLDs to demonstrate an effective decision support technique, the qualitative cause and effect diagram, which led to

sustainable and innovative management.

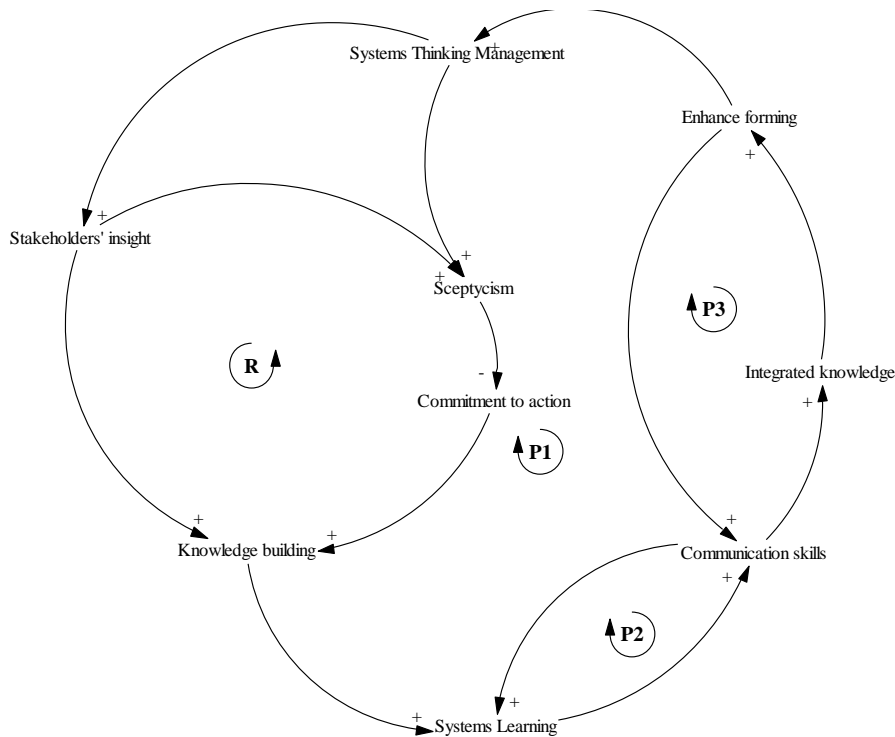

One of the well-known simulation modelling techniques is conceptual diagrams, which can unlock the decision-making process in a sustainable direction.

Business model innovation processes show that SD diagrams are a valuable tool for decision-making, improving managerial communication, strategies, knowledge integration, creative thinking, and evaluation of new business models.

Business model innovation processes show that SD diagrams are a valuable tool for decision-making, improving managerial communication, strategies, knowledge integration, creative thinking, and evaluation of new business models.

**Figure 5.** Dynamic diagram of a qualitative cause-and-effect system (Source: (authors, 2022))

Figure 5 shows the CLD model and the cause and effect of the imported facts, creating visible circular causality (loops), highlighted by a loop identifier, positive (reinforcing) or negative (balanced) feedback. The CLD does not show what is happening but what will happen if the variables change. The loops in the CLD are essential as they determine the system's behaviour. According to this model, managers can predict sustainable outcomes based on the interaction of cause-and-effect facts. An interpretation of the causal loop diagram (CLD) in Figure 5 would be as follows: Management with systems thinking influences (+) stakeholders' insights into systems increasingly, and they increasingly build knowledge about it (+). Knowledge increases (+) systems learning, which increases (+) communication skills and increases (+) integrated knowledge. Integrated knowledge has a positive effect

(+), and enhanced design affects the growth of systems thinking management (+). This description explains the reinforcement cycle, denoted by the symbol P. On the other hand, we have also anticipated the scepticism that is always present when change occurs. Systems thinking management increases (+) scepticism, but stakeholder insights also increase it (+), commitment to action decreases (-), and commitment to action has a positive effect on knowledge (+).

This description is represented by the equilibrium circle, denoted by the R. The causal loop model offers two more reinforcement circles, denoted by the symbols R2 and R3. Systems thinking increases (+) communication skills, and there is a growing return to systems thinking (+), which is becoming more and more understandable. Communication skills increase (+) integrated knowledge, which

has a positive impact on (+) enhanced modelling, which increases (+) communication skills. This qualitative description makes it possible to build a quantitative model in system dynamics. It can be said that the qualitative causal loop diagram forms the basis for a simulation model that can demonstrate the suitability of system modelling for sustainable innovation management. At once, it helps to bring about the desired systemic changes that are the key to individual and collective power of accountability (Zabukovec Baruca&Brezovec, 2014).

## 5. Conclusion

According to some authors (Košmrlj et al., 2015), the obstacles entrepreneurs meet when they try to solve problems of innovations are incorrect assessment of circumstances, insufficient data, information and analyses, and the importance of focusing

on the future. We can present and solve the problems by knowing a causal loop diagramming in a frame of system dynamics (CLD) since one of the most critical factors for sustainable management is feedback, especially the so-called balance loop. A negative or balancing loop, which emphasises system behaviour and enables management to make sustainable decisions, has the power to free complex systems, managers, and entrepreneurs to be sustainable and innovative.

Further research will address quantitative cause and effect diagrams by simulating the models developed. Thanks to visual diagrams acting as a knowledge interface between humans and machines, simulation software can implement system behaviour, test and evaluate the designed service of organisations and make sustainable decisions.

## **PRELIMINARY ASSESSMENT OF THE TECHNICAL CONSEQUENCES OF THE INCIDENTS ON THE NORD STREAM 1 AND 2 GAS PIPELINES. POSSIBLE WAYS OF SOLVING THE PROBLEMS**

***Abstract:** The incident on the Nord Stream pipeline system at the bottom of the Baltic Sea in 2022 caused a significant release of natural gas into the atmosphere and made it impossible to transport gas further through three of the four pipelines. Before the pipeline system was inspected and the results of the technical commission were available, a preliminary assessment of the volume of natural gas released was carried out, the possible technical consequences of the incident were evaluated and a preliminary assessment of the possibility of carrying out repair and restoration work was carried out. The existing technical solutions and alternative technologies to restore the pipeline system integrity have been analyzed. The feasibility of applying the technologies taking into account the specific conditions of the Baltic Sea has been evaluated. A preliminary assessment of the scope of repair works has been carried out and repair technologies have been considered.*

***Keywords:** offshore pipeline, calculation of gas leakage volume, offshore pipeline repair, offshore pipeline incident, Baltic Sea oil and gas infrastructure*

### **1. Introduction**

The Nord Stream pipelines are complex technical facilities designed and built in 2006-2012 and 2014-2021. They are the longest uncompressed gas pipelines in Europe. The length of these pipelines is about 1,224 km of each of the strings. The internal diameter is Ø 1,153 mm. Each of the four pipelines previously had an annual capacity of 27.5 billion cubic meters of gas. The design pressure varied from 220 bar at the Russian onshore compressor station exit to 106 bar at the Greifswald onshore exit in Germany: Kostianov A. G., Ermakov P. N.,

Soloviev D. M. (2008). The September 2022 accident resulted in the shutdown of natural gas from Russia to Europe via the Nord Stream pipeline system. Pipeline ruptures resulted in complete depressurization of the system, loss of a number of pipeline fragments as a result of explosions, destruction of the base and backfill of the pipeline sections. The works to establish the causes of the accident and assess the technical condition of the pipeline system will continue for an indefinite period of time. At the same time the technical specialists face a number of nontrivial problems which require additional research, analysis,

---

<sup>1</sup> Corresponding author: Pavel Shcherban  
Email: [ursa-maior@yandex.ru](mailto:ursa-maior@yandex.ru)

discussion and development of the concept of repair-rehabilitation work at these objects. Such works and actions are rare in the world practice and are of significant interest both in terms of offshore oil and gas technologies, engineering, mechanics, and in terms of ecology, economics, and organization of technological processes in general.

The raised problems are extremely extensive and surely will be widely discussed in scientific journals in the nearest future, especially taking into account new data and results of researches. The uncertainty of available information, the difficulty of organizing pipeline inspection processes, analyzing the data obtained and the importance of developing the concept of equipment rehabilitation, made the authors to summarize the technical data on the gas transportation systems of Nord Stream as of the beginning of 2023, as well as the task of assessing the possible consequences of the emergency situation and, as a result, developing recommendations for the maintenance of these pipeline systems. It should be noted that, in fact, each realized project of offshore hydrocarbon transportation system is individual, because it is necessary to take into account not only specifics of equipment materials, but also depths, winds, currents and characteristics of the bottom of the water area (Rosicki R., Rosicki G. *Znaczenie*, 2012). Therefore, the experience of emergency situations, their consequences and peculiarities of the approaches related to offshore pipeline systems repair can be used only partially. Among the most remarkable incidents of this kind are pipeline ruptures in the North Sea at the Dutch and British gas fields in the 1980s (Catherine Mitchell JimSweet TimJackson, 1990), gas pipeline ruptures in the Kara Sea (Bovanenkovo-Ukhta in 2018), gas pipeline ruptures in the Gulf of Mexico (the latest case in 2021 with the inflammation of gas released from the destroyed offshore pipeline of Petr6leos Mexicanos). In the scientific

and technical literature, the incident rate of the offshore oil and gas pipelines varies depending on the pipeline diameter and operating conditions in the range of  $1 \cdot 10^{-5}$  to  $1 \cdot 10^{-3}$  (events/year) /km.

In order to conduct a detailed analysis of the technical condition of the pipeline system after the incident and assess the repair options, we first consider the characteristics of the pipes and coatings used in the project, the specifics of the technology used during the construction of laying and placement of pipelines on the seabed, which will give a clearer picture of the original technical and hydrological characteristics of the strings of Nord Stream 1 and 2 gas pipelines.

## **2. Linear part of the Nord Stream pipeline system. Technical characteristics and breakdown points.**

When designing the Nord Stream pipeline route, a number of parameters were taken into account. They include not only the minimum distances along the pipeline route, but also the depths of the sea in the area of the pipeline route, the underwater relief, the presence of debris, shells, chemical weapons dumped since World War II, benthic communities, etc. (Värk J., Nutt M., Martin J., 2011). To improve safety and reliability of the system before design and construction, we collected geotechnical, environmental, bathymetric, and other baseline data with the participation of the Shirshov Institute of Oceanology of the Russian Academy of Sciences (IO RAS) and the Russian Federal Research Institute of Fisheries and Oceanography. The environmental feasibility study, risk assessment and quality management were carried out with the participation of Marin Mätteknik, Rambøll, DoF, PeterGaz, ERM, DNV, etc.

The bottom of the Baltic Sea is composed of different types of rock, it has prominent

ridges, hollows, crevices, quicksands and muds and it is not always possible to lower the pipeline directly onto these soils. Technically, if there is a big sag of the gas pipeline string between two natural supports, its construction can collapse over time (Dadonov Yu.A., 2008). That is why after the route was finally chosen the bottom relief in the laying zone was corrected artificially, by means of creating stable foundations preventing sagging, rolling and siltation of pipes. During the construction of each of the pipeline strings, a special vessel loaded with gravel and small stones, using a pipe, the lower end of which was equipped with nozzles, filled the bottom cavities, giving it a more suitable profile (Dantsevich I. M., Kosolap Y. G., Cherkasov A. V., 2021). Sometimes concrete slabs were lowered down instead of stones, to strengthen the base of the pipeline. In a number of sections, the buried location of the pipeline strings was preferred. Thus, along the entire route the bottom structure was checked and strengthening works were carried out. Different layouts were used depending on the type of seabed. In the northern part of the pipelines (Gulf of Finland area), due to the rocky ground, the pipelines were placed through bunding on the seabed as well as via a bunding scheme with a reinforced block base; in the central area of the Baltic Sea, a simple bottom placement with an additional weight coating was used more frequently as well as bunding in some places. In areas with heavy shipping traffic, on fairways and main port traverses (where soils allowed), the buried pipeline option was used. Considering the damage points of the gas pipeline strings, we can state that the emergency situation is localized in the areas where the laying was carried out in areas where the pipeline was simply placed on the bottom with an additional weighting coating. Special pipes with an outside diameter of 1220 mm and an inside diameter of up to 1153 mm were used in the linear part of the Nord Stream

pipeline. The pipe wall thickness varied depending on the depth of the pipeline installation and the pressure of the pumped gas. The pipe was designed to withstand a pressure of 220 bar in the first 300 km, 200 bar in the next 500 km, and 170 bar thereafter. On each of these sections the pipeline wall thickness varies from 34 to 27 millimeters.

**Table 1.** Key data on pipe manufacturers used in the Nord Stream 1A, B and Nord Stream 2A projects

Gas pipeline	Nord Stream 1 A	Nord Stream 1 B	Nord Stream 2 A
Pipe manufacturers	Europipe - 75% Vyksa Steel Works - 25%	Europipe - 65% OMK - 25% Sumitomo - 10%	Europipe - 40% OMK - 33% CHTPZ - 27%
Manufacturers of related materials - coating, cement, reinforcement	Saipem; Allseas; Van Oord; Boskalis Tideway; Rohde Nielsen		

This segmentation made it possible to save on the production costs of the pipes while maintaining their reliability. The maximum sea depth at the pipeline strings was 210 meters. The pipelaying was carried out in accordance with DNV OS-F-101 Submarine pipeline systems. The materials (steel pipes) used for construction of the pipelines were made by a number of companies (Table 1) in accordance with the international standard - ISO3183-3 Petroleum and natural gas industries - Steel for pipelines. The grade of steel used for main pipelines - SAWL 485 I FD - has three-layer external and internal antifriction coating (thickness from 90 to 150 microns), pipe length 12.2m with minimum yield strength of 485 MPa, submerged arc welding with one longitudinal seam capable of bearing a load of 570-605 MPa was carried out. The steel used in pipe

production is unique, and during its manufacture special importance is given to metal desulfurization process, which is carried out in three stages, which allows to obtain a material having very low sulfur content (not more than 0,0015%), the content of other impurities is also within narrow limits (Dantsevich I. M. et al., 2021). The outer surface of the pipes has an anti-corrosion component consisting of a three-layer polyethylene coating (3LPE) including epoxy resin (inner layer), adhesive layer and high-density polyethylene (outer layer), then there is a concrete coating over the anti-corrosion coating on the main pipes, whose task is to weight the pipeline for a stable position on the seabed (Lohmann S., 2019) (Figure 1).

**Figure 1.** Structure of internal and external pipe coating of the Nord Stream pipeline system.

Source: North Stream AG

In addition to cement, water and standard aggregates (gravel, crushed stone, sand), aggregate containing iron ore is added to the concrete mixture to increase its density; the concrete coating is also reinforced by a framework having welded steel rods (the minimum diameter of the rod is 6 mm). After welding the concrete coated pipes, the joints are protected with a heat shrink sleeve and highdensity polyethylene, then, as a frame, a sheet of carbon steel or polyethylene formwork is installed around the joints; after installing the frame, the voids formed between the heat shrink sleeve and the frame are filled with two-component polyurethane foam, which has a density of 160 kg/m<sup>3</sup> after hardening.

The chosen system combines a base layer of fusion-bonded epoxy coating (FBE) 0.15-0.30 mm thick, which is slightly less than the thickness of a standard base layer of three layers of polyethylene. A 0.2-0.4 mm thick Borcoat ME0420 (a binder made of polyethylene modified with maleic anhydride) from Borealis and an outer layer of Borcoat HE3450 (black, bimodal, copolymer high density polyethylene), also from Borealis, was applied over the base layer. RM7405 (so called coarse coating) of black polyethylene from Borealis was used as a cover layer. This coarse polyethylene layer, applied on the still hot outer layer, is designed to increase the adhesion to the subsequent concrete layer with a thickness of 60-110 mm.

The total thickness of the polymer coating is about 4.2 mm.

**Figure 2.** Depth of Nord Stream 1A and 1B.  
 Source: North Stream AG

The pipeline sections passing in the deepest areas are equipped with bend protectors, so-called deformation dampers, directly welded into the pipe and made of the same alloy, steel as the main pipes, but with a thicker wall and more delicate machining at the ends in order to match the main pipes.

**Figure 3.** Depth of Nord Stream 2A.  
Source: North Stream AG

Let's consider the bathymetric characteristics of the position of the Nord Stream 1 and 2 pipes (Figures 2 - 4). The total thickness of the polymer coating is about 4.2 mm. The pipeline sections passing in the deepest areas are equipped with bend protectors, so-called deformation dampers, directly welded into the pipe and made of the same alloy, steel as the main pipes, but with a thicker wall and more delicate machining at the ends in order to match the main pipes. Let's consider the bathymetric characteristics of the position of the Nord Stream 1 and 2 pipes (Figures 2 - 4). Given the coordinates of the incident points, we can say that in the case of the North Stream 1 string A, the pipeline failure occurred at a depth of -85 m. In the case of string B, the pipeline rupture occurred at a depth of -84 m. In the case of Nord Stream 2 A, the pipeline breakdown occurred at a depth of -87 m and -73 m.

As for the peculiarities of Nord Stream pipeline design, it should be noted that apart from primary corrosion protection, it has secondary protection, which is provided by anodes made of galvanic material (Chen B. Q., Zhang X., Soares C. G., 2022). This protection represents a separate (independent) system, the effect of which is

aimed at pipeline protection in case of damage of external pipe coating.

**Figure 4.** Breakdown points on gas pipelines and depths  
Source: Authors

Anode alloys for preserving pipeline integrity for the calculated operation time have been determined by tests, the results of which showed that zinc alloy is appropriate for the sections with low and medium mineralization, for the remaining sections the use of indium-activated aluminum has been declared (Aulia R., Tan H., Sriramula S., 2021).

Taking into account the technical characteristics of the Nord Stream pipeline system, as well as the location of failure points, sea depths, peculiarities of the location of pipelines on the bottom, we will make two types of calculations. First, we preliminarily estimate the volume of natural gas release from each of the pipeline strings, and second, we consider the issue of repair and restoration work volumes by calculating the lengths of destroyed and flooded sections.

### 3. Preliminary assessment of the consequences of the gas pipeline system destruction

To make the calculations, we consolidate the materials on the technical parameters of the pipeline and the external environment in all damaged sections. Then we calculate the

leakage volume from section to section and make a preliminary assessment of the length of flooding of each of the pipeline strings - both by sections from the gas supply point and by sections adjacent to the receiving point (Maksimov A. O., Polovinka Y. A., 2015; Podvalny S., Kutsova E., Vasiljev E., 2021), (Figure 5).

**Figure 5.** Example of the location of sections of the Nord Stream-1A pipeline, in relation to the incident point.

Source: Authors

The distance from the place of the gas pipeline rupture to the nearest emergency valves is marked  $x_1$  and  $x_2$ .  $L_1$  and  $L_2$  are distances from the place of rupture to compressor stations.

At the first stage let us determine the initial critical gas flow rate (STO Gazprom 2-3.5-051-2006; Kóczy L. Á., Cserssik D., Sziklai B. R., 2022) (1):

$$G_0 = \frac{P_0 \cdot \pi \cdot d_0^2 \cdot \sqrt{k}}{4 \cdot \sqrt{R \cdot Z_k \cdot T_0^m}} \cdot \left[ \frac{2}{k+1} \right]^{\frac{k+1}{2 \cdot (k-1)}}, \#(1)$$

Where:  $P_0$  - pressure at the moment of the incident at the point of gas pipeline rupture (Pa);  $d_0^2$  - pipe inner diameter (m);  $k$  - gas adiabatic index (b/r);  $R$  - gas constant (J/(kg·K));  $Z_k$  - gas compressibility factor in the critical section;  $T_0^m$  - average temperature (K).

Thus, the gas flow rate for the first damaged section with the length  $L_1$  will be determined by the expression:

$$G_1(t \leq t_l) = \frac{M_n}{\eta_L^2 \cdot \varepsilon_L} \cdot \exp \left[ -\frac{1}{\eta_L^2 \cdot \varepsilon_L} \right] + \frac{[M_g - M_n]}{\varepsilon_L} \cdot \exp \left[ -\frac{t}{\varepsilon_L} \right], \#(2)$$

Where:  $t_l$  we assume more than 0.1s;  $M_n$  - mass of gas flowing in adiabatic mode (kg);  $M_g$  - mass of gas in the damaged section of the pipeline (kg).

The value of  $\eta_L$  is determined according to the expression (3):

$$\eta_L = \frac{2 \cdot M_g}{\varepsilon_L \cdot G_0}, \#(3)$$

Where:  $\varepsilon_L$  - time constant, s.

In this case, depending on the section, it is determined by the following ratio:

$$\varepsilon_L = \frac{2}{a_0} \cdot \frac{L_1}{d_0} \cdot \sqrt{\frac{k \cdot \lambda \cdot L_1}{d_0}}, \#(4)$$

Where:  $a_0$  - speed of sound in the gas before the incident;  $\lambda$  - hydraulic resistance coefficient.

**Figure 6.** Destruction of the Nord Stream-1 pipeline section, initial inspection results  
Source: Nord Stream AG

Further in the calculation it is necessary to take into account the mass of gas at the point before the incident (kg):

$$M_g = \frac{L_1 \cdot \pi \cdot d_0^2 \cdot P_1^m}{4 \cdot R \cdot Z_0^m \cdot T_1^m} \pm M_{ks}, \#(5)$$

Where:  $Z_0^m$  – the compressibility factor of the gas before the incident at the parameters  $P_1^m$  and  $T_1^m$ ;  $M_{ks}$  – mass of gas (kg) pumped into the first section of the pipeline by the compressor station until the cut-off of the damaged section, kg. The sign "+" is used in calculations for the first damaged section, the sign "-" in calculations for the second damaged section.

$$M_{ks} = G_{ks} \cdot t_i, \#(6)$$

Where:  $G_{ks}$  – the pipeline capacity in normal operating mode (kg/s);  $t_i$  – time from the moment of the incident till the stationary

emergency valve is completely closed (s).

Then using formula (7) it is necessary to determine the mass of gas flowing in adiabatic mode:

$$M_n = \frac{2 \cdot M_g \cdot d_0}{\lambda \cdot L_1 \cdot \sqrt{k}} \cdot \left\{ \left[ \frac{1}{k} \cdot \left( \frac{k+1}{2} \right)^{\frac{k+1}{k-1}} + \frac{\lambda \cdot L_1}{d_0} \right]^{\frac{1}{2}} - \left[ \frac{1}{k} \cdot \left( \frac{k+1}{2} \right)^{\frac{k+1}{k-1}} \right]^{\frac{1}{2}} \right\}, \#(7)$$

To determine the mass of gas at the gas release from the first section until the line valve is closed, we use the expression (8):

$$M_{11} = M_n \cdot \left( 1 - \exp \left( -\frac{t_l}{\eta_L^2 - \varepsilon_L} \right) \right) + (M_g - M_n) \cdot \left( 1 - \exp \left( -\frac{t_l}{\varepsilon_L} \right) \right), \#(8)$$

Next, to determine the total volume of gas leakage it is necessary to establish the value of its flow at the time of closing the damaged section, which can be done by the following formula (9):

$$G_1(t_l) = \frac{M_n}{\eta_L^2 \cdot \varepsilon_L} \cdot \exp \left( -\frac{t_l}{\eta_L^2 \cdot \varepsilon_L} \right) + \frac{(M_g - M_n)}{\varepsilon_L} \cdot \exp \left( -\frac{t_l}{\varepsilon_L} \right), \#(9)$$

Since the emergency shutdown system is triggered when the gas pipeline is damaged, it is necessary to calculate the gas flow rate for the damaged section 1 after closing the valve:

$$G_1(t > t_l) = G_1(t_l) \cdot \exp \left( -\frac{t - t_l}{\varepsilon_x} \right), \#(10)$$

Where:  $\varepsilon_x$  – time constant

$$\varepsilon_x = \frac{2 \cdot x_1}{3 \cdot a_x} \cdot \sqrt{\frac{k \cdot \lambda \cdot x_1}{d_0}}, \#(11)$$

Where:  $a_x$  – sound velocity in the cut-off section at the time  $t_{ij}$ :

$$a_x = \sqrt{k \cdot R \cdot Z_0^m \cdot T_{ch}^m}, \#(12)$$

Where:  $T_{ch}^m$  – average temperature in the cut-off section after closing the line valve (K).

The mass of gas in the second phase of the flow after closing the line valve is calculated by the formula (13):

$$M_{12} = \varepsilon_x \cdot G_1(t_l), \#(13)$$

Total mass of gas on the first incident section (14):

$$M_1 = M_{11} + M_{12}, \#(14)$$

For the second cutoff section, we perform the same calculation. The intensity of gas outflow in each of the strings during the incidents on the North Stream 1 and 2 are shown in the graphs (Figures 7 - 9). We assume that the time passed from the moment of the incident to the moment of complete closure of the line valves at both sections of the pipeline is 40 sec. For the second section of length x2 the calculations are made in the same way (Lurie M. V., Musailov I. T., Lysenko N. O., 2020).

**Figure 7.** Graphs of natural gas leakages from the damaged pipeline segments of the Nord Stream 1A pipeline: a - section of the pipeline from the gas compressor station in Russia to the rupture place; b - section from the rupture place to Greifswald. Source: Authors

Certainly, it should be noted that the indicated volumes based on the results of calculations are based on open data and were obtained considering the above-mentioned calculation methodology.

**Figure 8.** Graphs of natural gas leakages from the damaged pipeline segments of Nord Stream 1B: a - section of the pipeline from the gas compressor station in Russia to the rupture point; b - section from the rupture point to Greifswald). Source: Authors

Results may differ significantly in case of other technical characteristics or other methods (STO Gazprom 2-3.5-051-2006). The final results will be obtained by visual inspection and inspection. Data obtained using the above mentioned, methodology for natural gas leakage volumes and the length of pipeline strings flooding were summarized in the following table (Table 2).

**Figure 9.** Diagrams of natural gas leakages from the damaged pipeline segments of Nord Stream-2A: a - section of the pipeline from the gas pumping station in Russia to the rupture point; b - section from the rupture point to Greifswald).

Source: Authors

**Table 2.** Preliminary volume of natural gas leakage from damaged strings of the Nord Stream system. Estimated volume of repair and rehabilitation work.

Pipeline string	NS-1A	NS-1B	NS-2A
mass of the gas during the total time of outflow (in mega tons)	0,018217	0,017851	0,044246
mass of the gas during the total outflow time (in mega tons)	0,0803		

Using the results of calculations we can preliminarily assert that the volume of methane emission caused by all incidents was about 0,0803 mega tons, emissions of different intensity took place over a period of 4-6 days. At the same time, no more than 10% of the gases dissolved in the sea water, and the main mass was released into the atmosphere.

In general, the total volume of leakages corresponds to the volumes of emissions assumed by different expert organizations (Mehrafrooz B., Edalat P., Dyanati M., 2019). Thus, according to the calculations made by: Stéphane Orjollet in his publication dated October 5, 2022 "Nord Stream leaked less methane than feared: atmospheric monitoring" - the leakage volume in all pipeline sections was about 0.07 meg tons; according to the article "Improved estimates of Nord Stream leaks" by Christine Forsetlund Solbakken dated October 12, 2022: the leakage volume from all damaged sections was 0.056 - 0.155 meg tons. Interested results of gas leakage was shown by Katharine Sanderson, they are also confirming presented calculations (Sanderson, Katharine, 2022).

#### 4. Analysis of the application of different methods for gas pipeline restoration on the bottom of the Baltic Sea

The investigated emergency situations require decision-making on carrying out repair-rehabilitation works on the gas pipelines of the Nord Stream system. At the same time we can state that after direct visual inspection of pipelines, their sonar sounding, metal sampling and establishing the actual length of flooded sections, a number of obligatory operations will be required at the transition stage before repair works:

1. Restoration of at least 100-150 meters of embankments under pipeline strings in emergency areas;
2. Dismantling of destroyed and flooded sections of pipelines;
3. Preparation of pipeline sections for repair works;
4. Carrying out works on connection of broken sections (installation of new section of pipes instead of lost ones);
5. Carrying out of external and internal diagnostics of gas pipeline strings, testing;
6. Obtaining of the special permission documents for putting into operation after the execution of the repair-restoration works and registration of the insurance.

It should be noted that, in fact, each of these stages requires a separate investigation, as it is connected with the solution of a large number of technical, technological, organizational, managerial and political problems. Nevertheless, the technical and technological aspect of the problem results in choosing the optimal method of repairing the damaged pipeline strings. At the same time it is obvious that the repair works on the Nord Stream-2A pipeline is unreasonable due to the high length of the flooded section (over 105 km), as well as the absence of permits for putting the pipeline into operation (insurance). In the case of Nord Stream-1A, B pipelines the repair is possible by applying such technologies as Heier E., Mellem T. (2007):

1. Underwater welding operations with cut-in points and hyperbaric chambers (e.g. application of PRSI - Pipeline Repair and Subsea Intervention or Eni/Saipem SiRCoS - Sistema Riparazione Condotte Sottomarine)
2. Lifting and welding of the pipeline strings on the surface, with subsequent laying

Now let's analyze the application of these methods, their strong and weak points, as well as the risks associated with the repair process of the gas transportation system. We should note that some of the presented technologies have already been used during the pipeline construction.

For example, hyperbaric welding was performed at three points along the route of each of the pipeline strings. The welding works were remotely monitored by the Skandi Arctic, while divers performed the monitoring and control of the welding of the sections themselves. These cases (for any of the pipeline strings) allow this type of work to be carried out because the depth of the incident does not exceed 180 m. (depth limitation for divers, according to DNV-RP-F113 Pipeline subsea repair).

**Figure 10.** a - North stream pipeline bracing by hyperbaric welding; b - PHF; c - PRS.

Source: a- Nord Stream AG, b, c – Authors

In technological terms, the process is as follows. A specialized welding equipment is lowered on the sea floor, to the area containing the retained section, which has been cleaned and prepared by the divers; this is where the old section and the new section lowered from the ship can be welded (Amaechi C. V., Hosie G., Reda A., 2023).

The specialized dry-welding system used during construction of the Nord Stream pipelines was previously supplied by Statoil. It is a dry zone (PRS), where divers work without diving equipment to set up the automatic welding machine. At the same time, the welding process is fully controlled from the support vessel. At the same time, two specialized supporting mechanisms (PHFs) are lowered onto the same seabed area, which provide support and alignment of the welded pipeline strings (this is necessary to ensure the quality of the welded joint).

There are different modifications of such technological scheme of repair performed by companies. Thus, the repair can be carried out with or without the use of divers - for example, with the use of special robots, with the involvement of various support and alignment systems and with special telemetry systems. In general, we can distinguish three large groups of companies that provide such technologies - Norwegian, Italian and American companies. Whether it is possible to carry out such repair and restoration work under current conditions with the involvement of partners from these countries is an open-ended question.

Another method of repairing damaged sections of gas pipelines is surface repair, using specialized vessels (Sharifi S. M. H., Kaveh M., Bolfakeh M., 2022). Considering the process of welding area preparation, welding operations and subsequent flaw detection, as well as pipeline coating operations - this method allows to achieve higher quality and reliability and fully meets the requirements of DNV-OS-F101:

Submarine Pipeline Systems. However, we should mention some specific aspects that may complicate this technological process. Initially, after inspection, clearing and elimination of the damaged pipeline section, cleaning and fastening of the repaired pipeline to the hoists is performed (Figure 11 a).

During this operation, the integrity of the lifted pipe string, the uniformity of fastening and distribution of loads during the lifting of the pipeline section are of great importance. Then, additional pipes are delivered to extend the pipeline (Figure 11 b).

**Figure 11.** a. Lifting the flooded pipeline from the seabed; b. Bringing in additional pipes for welding on the surface

Source: Authors

At the same time the lifted pipe section is gradually filled with gas to be lifted aboard the ship. Next step is onboard inspection and inspection of the welded-on string, removal of protective coating on the end section, and subsequent onboard welding and joint assembling of the sections on the ship (Figure 12 a). This ensures their alignment, quality of edge stripping, quality of welded joints and protective coating.

**Figure 12.** a. Emptying of the pipeline, inspection, preparation for welding, welding of new sections; b. Connection of the expanded section and the second end of the gas pipeline  
 Source: Authors

At the final stage, welding is performed with the opposite old section, which is also lifted from the bottom, with the performance of the whole complex of measures for its examination and preparation for joining (Figure 12 b). After that, the final welding, weld quality control, coating with external protective coatings, lowering and laying on the bottom, with subsequent tests take place. In fact, this work was already performed during the construction of the Nord Stream pipeline, involving specialized vessels: Castoro Sei, Far Samson, Allseas' Solitaire, as well as many other tugs, supply vessels, and soil preparation vessels. Of course, arrangement of works using this technology will also require consolidation of efforts at the international level. At the moment, unfortunately, the Russian Federation doesn't have a fleet capable of handling the whole range of operations. However, there are plenty of contractors (as compared to underwater hyperbaric welding) in this case - a number of firms and companies in East Asia, South America and, of course, in Europe.

In this regard, it is more rational to repair and restore the damaged sections of the Nord Stream pipeline by repairing it on the surface (due to the complexity of contracting,

organization of the technological process, and the quality of the work itself).

A preliminary analysis of the scope of work shows the necessity of forming a group of vessels to provide not only lifting and welding of the strings, but also clearing and strengthening the bottom in the emergency areas (for the strings of Nord Stream 1, this will be about 2 km). Strengthening and restoration of the embankment - about 120 km, with clearing of flooded pipes. In addition, material support is required - production and delivery of the proper amount of pipes, fittings, concrete, gravel and electrodes. So, according to preliminary assessment (excluding a direct underwater inspection), the restoration of both strings of Nord Stream-1 will require at least 9837 pipes

## 5. Conclusion

Initial analysis suggests that about 0,0803 meg tons of natural gas was released into the atmosphere as a result of the incident on the three strings of the Nord Stream pipelines. Preliminary modeling shows that gas release from the breakdown points continued for up to 6 days. If the valves in the pipeline sections had operated normally, after the shutdown the volume of flooding was about 60 km in the pipeline sections Nord Stream 1A and B, and about 110 km in the pipeline section Nord Stream 2A. (taking into account the pipe section between the two incident points).

If the pipeline valves were not closed, the gas release could last longer and be larger in volume, and the flooding process of the pipeline strings took place up to the hydrostatic pressure level - between the sea water and the gas remaining in the system. Considering the relatively shallowness of the seabed in the area of the Bornholm basin - based on data from bathymetric maps, it is impossible to establish these hydrostatic pressure levels in an analytical way. More

precise results can only be obtained by direct underwater inspection of the pipeline strings. Taking into account the complexity and high cost of repair and restoration of pipelines, it seems rational to repair only the Nord Stream-1A and B gas pipeline strings. In this case, the most affordable and at the same time controllable and qualitative way of repair will be lifting of flooded strings on a ship, its inspection, repair, extension, welding and lowering onto a prepared ground. To perform these works a wide

range of contractors can be involved. It should also be noted that application of this technology will provide a full range of tests of the system after welding works in accordance with the requirements of DNV-RP-F113 Pipeline subsea repair.

## THE BIDIRECTIONAL RELATIONSHIP BETWEEN HIGHER EDUCATION AND INNOVATION: EMPIRICAL EVIDENCE FROM MENA REGION

**Abstract:** *The purpose of this paper is to examine the bidirectional relationship between two sets of variables, higher education and training (eight indicators) and innovation (seven indicators), using the canonical correlation analysis (CCA). The study utilises data published by the World Economic Forum Reports for seven years (2012-2018) for a sample of 12 countries in the MENA area. CCA is used to analyse the relationship between the two sets of variables. It helps in the evaluation of the interchangeable relationships between the two sets of multiple variates. More in-depth analysis of the nature of such a relationship between the two sets of variables is provided through redundancy analysis to identify the percentage of the variance in each set that is interpreted by the other set, and the commonality analysis to determine the variance of canonical function that is due to unique or standard variables. Canonical analysis shows the causality between the two endogenous sets of variables. Also, the findings suggest that technology alone is not an antidote, while other factors might have a significant impact on innovation. Commonality analysis shows that the role of quality of management school in explaining the variation in canonical function of innovation in common with “quality of education system”, “quality of math and science”, “internet access”, “training availability and “staff training produce”.*

**Keywords:** *Higher Education and Training, Innovation, Canonical Correlation Analysis, Emerging Markets*

### 1. Introduction

Higher education plays an essential role in the economic development of countries worldwide. It is a fundamental and reliable axis to achieve prosperity and progress. Higher education institutions need help with many problems, including adherence to tradition, which is one of the obstacles to universities benefiting from innovation and technology. For example, innovation is likely to make a massive difference in our world as it can help to develop and

overcome any new risks the world may face (Bates, 2009). According to Arima (2002), the needs of societies are continuously changing. Consequently, there is need to rethink university education's purpose education. Although higher education has evolved over the centuries to keep pace with changes in societies, it still needs to be improved for some curricula in addition to the development of new curricula where universities must adopt technology-based innovation in many educational materials to fill some gaps in higher education.

Wildavsky et al. (2012, p. 1) pointed out that “higher education has to change. It needs more innovation”. The integration of modern information technology-based innovation in educational processes helps to acquire knowledge easily. Therefore, educational institutions can meet the needs of the labour market with qualified graduates (Cai et al., 2019). In this regard, Gourova et al. (2014) concluded that higher education institutions play an exclusive role to their customers including public and private firms through the transfer of knowledge. Such knowledge is essential for countries tilling to achieve advanced economies and prosperity for their people. This requires the availability of well-educated and well-trained workers to perform complicated tasks using advanced technology-based innovation that is rapidly adapted to their changing environment and evolving labour market needs. Several studies have addressed the relationship between higher education and innovation from one direction (Goddard & Vallance, 2013; Etzkowitz, 2013; Buasuwan, 2018; Cai et al., 2019; Cai et al., 2020).

The current study investigates the bidirectional relationship between higher education and innovation, in addition, it provides a deep analysis of the nature of such relationships using unique analyses namely, the canonical correlation, redundancy, and commonality analyses. In this regard, we considered the main ideas for both social cognitive theory and constructivist theory by selecting eight indicators for higher education & training factors. The nature of these indicators is related to the external environment and personal aspects such as “quality of the education system”, “quality of math and science education”, “quality of management schools”, “Internet access in schools”, “local availability of specialized training services” and “extent of staff training”. The above-mentioned indicators have been suggested by the World Economic Forum (WEF) to reflect

the competitive characteristics of countries. Furthermore, the study calls to apply technology-based innovation to improve higher education as a new stream for the future. Such a stream can affect the ability to innovate because it reflects the extent to which professional researchers can benefit from technology in creating new ideas, ways, or new products and moreover, its effects on labour market efficiency (Billon et al., 2017; Yunis et al., 2018).

Our study has unique characteristics over previous studies. First, it provides evidence of the bidirectional relationship between higher education & training set and innovation set. Whereas, previous studies, (Thor, 2011, Cai and Liu, 2015; Cai et al., 2020) on higher education and innovation, have examined the relationship between the two sets of variables from one direction. Second, this study uses a sample of 12 Middle Eastern countries that suffer from the lack of studies in this area of research, therefore, it provides a valuable contribution to the field of higher education & innovation. Third, the study uses a set of distinct measures to estimate higher education & innovation by adopting eight variables for the higher education & training set and seven variables for the innovation set. These two sets of variables have been suggested by the WEF to reflect the competitive advantages of each country which makes a clear difference between the current study and previous studies. Moreover, the data related to these variables have been collected by international organizations with a distinguished global reputation such as International Monetary Fund (IMF); the World Bank; and various United Nations’ specialized agencies which provide a high level of accuracy for such data. Fourth, the current study employs the canonical correlation analysis, as a unique statistical method to explore the bidirectional relationship between higher education & training set and innovation set in a sample of

12 the Middle East and North African countries (MEAN), and to determine the most common factors in each set and the percentage of the variance explained in each variable over the other. Moreover, it the redundancy, and commonality analyses to identify the percentage of variance and such variance is due to unique or common variables. Fifth, the results of our study may provide some avenues for regulators in MEAN countries to support both education and innovation in educational institutions, which has the greatest impact on the economic development of these countries and the achievement of a higher level of well-being for their people.

We are motivated to focus on MEAN by using a sample of 12 countries namely, Bahrain, Cyprus, Egypt, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Turkey, United Arab Emirates and Yemen. for several reasons. First, these countries have a common heritage of history, culture, trade relations and economic conditions, which makes the study sample is coherent and consistent. Secondly, these countries suffer from a shortage in the number of studies related to higher education and innovation, unlike most developed countries. Third, MEAN countries are a model for both developing countries and emerging markets as well. Since these countries are characterized by being attractive to foreign investment, the results of this study may be of interest to many different parties inside and outside these countries. The structure of the current study is as follows. Section 2 presents a literature review and hypotheses development. Section 3 offers details on the research methodology. The section shows data analysis and results. Section 5 concludes the study.

## 2. Literature Review and Hypotheses Development

### 2.1. The Impact of Higher Education & Training on Innovation

The topic of the university's role in creating innovation within societies is receiving a great and increasing attention, as the education reform process requires the interaction and integration of universities in their society with industry and other actors to enhance innovation (Mowery & Sampat, 2005; Etzkowitz, 2013). The educational system is one of the most important elements of the innovation system in any country. The effectiveness of the educational system depends on a range of factors including human resources and linking the adequacy of the education system with the requirements of the economy, nationally in particular and globally in general. For example, in China, Cai and Liu (2015) examined the effect of universities' role in innovation systems by considering universities' engagement with society to promote innovation systems. Magno and Sembrano (2007) argued that innovation is the ideas or methods conceived by innovators, then turned these ideas into new practices in recent years. Therefore, innovation is a tool that can be used by higher education institutions to adopt the requirements of societies and students to bring new changes in educational practices through the adoption of modern technology. There are different forms of educational innovations including innovative models of education; new textbooks and programs; new or improved learning technologies (such as distance or online learning and Internet technology); updating the content of the curriculum; new teaching technologies; ideological innovation; scientific and methodological innovation; managerial innovation and others. (Zhu, 2015; Buasuwan, 2018).

Universities are facing pressure from many external parties including the government and the public to change their strategy and adopt new policies that can enhance innovation in university education (Cai, 2017). Thus, to understand the innovation process in universities, Musselin (2007, p. 317) reported that “one has to take ‘two speeds’ of change into account”. Lundvall (2013, p. 33) pointed out that “as one that starts with combining elements of existing knowledge and ends with new knowledge as an important output”. This process is linked with the knowledge that can be gained by educational organisations therefore innovative ideas need educational interaction and good implementation of these ideas needs a learning process carried out by scientific bodies with accumulative experience in the field of innovations (Cai, 2017). Finally, Armstrong and Taylor (2000) identified several effects of the universities in their societies related to economic development in both the short and long term such as improving the quality of labour by providing quality skilled graduates and skilled workers to labour markets; and skilled staff to provide expert advice to regulators and agencies; enhancing the cultural and economic developments. Based on the above discussion, the first hypothesis is suggested as follows:

**H1:** Higher education & training has a significant impact on innovation.

## **2.2. The Impact of Innovation on Higher Education & Training**

According to Rogers (2003, p. 22), innovation is “the degree to which an individual or other unit of adoption is relatively earlier in adopting new ideas than other members of a system”. Braak (2001, p.144) also described innovativeness as “a relatively stable, socially-constructed, innovation-dependent characteristic that indicates an individual’s willingness to

change his or her familiar practices”. However, Goddard & Vallance (2013) argued that innovation in higher education is part of an intertwined and connected social system, and universities of course are part of this system, then innovation in higher education is seen as a response to changes in society and the economic system where universities play a vital through managing and transferring the knowledge economy. In this avenue, Billon et al. (2017) argued that innovations are the result of interactions between a range of socio-economic factors as well as research and development activities. Therefore, the economic and social development of societies affects the innovation process in higher education (Goddard & Vallance, 2013). Etzkowitz and Leydesdorff (1997) determined three main elements of the innovation system. Such elements are industry, university, and government. Innovations in higher education aim to have long-term effects. For example, universities are becoming increasingly intertwined with and supportive of industrial innovation ((Etzkowitz, 2003) similar argument was provided by Wang (2014).

Furthermore, Makori et al. (2013) reported that technology-based innovation is one of the most influential factors in societies and institutions, including educational institutions, especially in the twenty-first century with the knowledge-based economy. The concept of technology-based innovation reflects programs and services related to the circulation of information over the Internet, simulations and others. The process of integrating technology-based innovation with the educational process aims to take advantage of different technologies in transferring educational experiences through social networks, distance education, blogs and e-learning. Integrating technology with education increases innovation opportunities (Baer and McCormick, 2012). Technology-based innovation is the main driver of economic growth, social development of

people and good performance of business enterprises (Yunis et al., 2018). Such an argument is consistent with the European Commission (2010) which pointed out that the economic prosperity of the people of the European Union is fundamentally dependent on innovation and technology. Because they are sources of competitive advantage associated with local knowledge creation and knowledge diffusion that may increase competitiveness and economic growth at the regional level (European Commission, 2010). Innovations and technology services are commodities whose demand is positively affected by a combination of economic factors such as household income, gross domestic product (GDP) and unemployment (Vicente and López, 2011; Neokosmidis et al., 2015).

Furthermore, Zhu (2015) conducted survey research among six Chinese universities to examine the association between organisational culture and technology as well as, the implementation of innovation factors. The major finding of Zhu's study is that organisational culture has a significant impact on using technology in higher education, including online learning. Isleem (2003) investigated the use of technology-based innovation for educational purposes in "Ohio public schools" focusing on several factors such as the level of technology used by teachers, attitude, and the characteristics of teachers. The main finding of Isleem's study is that the greater the experience of the teacher with the computer, the greater his or her appetite for using the computer over teachers who lack the experience to deal with computers. Makori et al. (2013) examined the use of technology-based innovation in higher education, in two Kenyan universities, using different research methods such as a survey, interviews and document analysis. They revealed that where graduates lack the relevant technology knowledge and skills, there is an urgent need for technology-based innovation to be

integrated with higher education to meet the demands of the job market. According to above discussion, the second hypothesis is established as follows:

**H2:** Innovation has a significant impact on higher education & training.

### 3. Research Methodology

#### 3.1. Canonical Correlation Analysis (CCA)

CCA can be used "when you wish to analyse the relationship between two sets of variables" (Pallant, 2013, p. 102). It helps in the evaluation of the interchangeable relationship between two sets of multiple variates. It is a method of giving meaning of cross-covariance matrices (Hair et al., 2010). The main objective of CCA is to identify the best linear combination between the two sets of data that maximizes the linear correlation between them. One is a linear combination of the variates of the first set, and the other is a linear combination of the variates in the second set. Such that, If there are two sets of variates with each set consisting of two or more variates " $X=(x_1, \dots, x_i)$ " and " $Y=(y_1, \dots, y_j)$ ",  $i$  and  $j$  the numbers of variates in each set, the CCA can find the orthogonal linear transformation of  $X$  and  $Y$  that have the highest correlation coefficients with each other, if we have " $U=a'X$ " and " $V=b'Y$ ". The highest number of canonical functions that can be found equals the minimum variates in any set  $\min_{i,j} \{f_0\}$  (Stevens, 1996; Hair et al., 2010; Warner, 2008).

In the present study, CCA is used to identify the inter-relation between the two sets of variables. First set is "higher education & training" that includes eight variates namely, "secondary education enrolment rate gross % (SEER)"; "tertiary education enrolment rate gross % (TEER)"; "quality of the education system (QOES)"; "quality of math and science education (QMSE)"; "quality of

management schools (QOMS)”; “internet access in schools (IAIS)”; “local availability of specialized training services (LAST)” and “extent of staff training (EOST)”. The second set is “innovation” that includes seven variates namely, “capacity for innovation” (CFIN); “quality of scientific research institutions” (QSRI); “company spending on research and development (R&D)” (CSR D); “university-industry collaboration in R&D” (UCRD); “Gov’t procurement of advanced technology products” (GPAT); “availability of scientists and engineers” (ASAE); and “patent applications” (PATA). Since the present study has two sets of variates where the first set has seven variates and the second with eight variates, therefore the number of canonical functions is equal to the number of variates in the smaller set ( $\min\{7,8\}=7$ ). All the analyses in the present study were done using the package CCA in R-software (<http://cran.r-project.org/>).

**3.2. Data Collection and Sample Size**

Our sample includes 12 countries from MEAN area namely, Bahrain, Cyprus, Egypt, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Turkey, United Arab Emirates and Yemen. Data needed for variables of the study (set 1: “higher education and training” and set 2: “innovation”) were collected from WEF Reports covering the period from 2012 to 2018. These variables are pillars of the Global Competitiveness Index (GCI) that was established by WEF.

**3.3. Measurement of the variables of the study**

The measurement of two sets of variables used in this study is based on the data collected from “Global Competitiveness Reports” related to seven years (from 2012 until 2018) that established by WEF through GCI. Details on these sets and their variables are shown in Tables 1 & 2 below.

**Table 1. Higher education & training (the first set)**

The first set: Higher education & training (“X”)			
No.	Variable	Notation	Description
1	“Secondary education enrolment rate gross percentage” (hard data)	SEER “X1”	“According to the World Bank’s World Development Indicators, this corresponds to the ratio of total enrolment, regardless of age, to the population of the age set that officially corresponds to the secondary education level.”
2	“Tertiary education enrolment rate gross percentage” (hard data)	TEER “X2”	“According to the World Bank’s World Development Indicators, this corresponds to the ratio of total enrolment, regardless of age, to the population of the age set that officially corresponds to the tertiary education level”
3	“Quality of the education system”	QOES “X3”	“How well does the educational system in your country meet the needs of a competitive economy? [1 = not well at all; 7 = very well]”
4	“Quality of math and science education”	QMSE “X4”	“How would you assess the quality of math and science education in your country’s schools? [1 = poor; 7 = excellent – among the best in the world]”
5	“Quality of management schools”	QOMS “X5”	“How would you assess the quality of management or business schools in your country? [1 = poor; 7 = excellent – among the best in the world]”
6	“Internet access in schools”	IAIS “X6”	“How would you rate the level of access to the Internet in schools in your country? [1 = very limited; 7 = extensive]”
7	“Local availability of specialized training services”	LAST “X7”	“In your country, to what extent are high-quality, specialized training services available? [1 = not available; 7 = widely available]”
8	“Extent of staff training”	MOST “X8”	“To what extent do companies in your country invest in training and employee development? [1 = hardly at all; 7 = to a great extent]”

Source: “Global Competitiveness Report (from 2012 to 2018). “World Economic Forum”; available at: <https://www.weforum.org>”

**Table 2.** Innovation (the second set)

The second set: Innovation (“Y”)			
No.	Variable	Notation	Description
1	“Capacity for innovation”	CFIN“Y1”	“In your country, companies obtain technology (1 = exclusively from licensing or imitating foreign companies, 7 = by conducting formal research and pioneering their own new products and processes)”
2	“Quality of scientific research institutions”	QSRI“Y2”	“Scientific research institutions in your country (e.g., university laboratories, government laboratories) are (1 = nonexistent, 7 = the best in their fields internationally)”
3	“Company spending on R&D”	CSR“Y3”	“Companies in your country (1 = do not spend money on research and development, 7 = spend heavily on research and development relative to international peers)”
4	“University-industry collaboration in R&D”	UCRD“Y4”	“In the area of R&D, collaboration between the business community and local universities is (1 = minimal or nonexistent, 7 = intensive and ongoing)”
	“Government procurement of advanced technology products”	GPAT“Y5”	“In your country, government procurement decisions result in technological innovation (1 = strongly disagree, 7 = strongly agree)”
6	“Availability of scientists and engineers”	ASAE“Y6”	“Scientists and engineers in your country are (1 = nonexistent or rare, 7 = widely available)”
7	“Patent applications” (hard data)	PATA“Y7”	“Number of utility patents (i.e., patents for invention) granted between Beginning of year, January 1, to end of year, December 31, per million population”

Source: “Global Competitiveness Report (from 2012 to 2018). “World Economic Forum”; available at: <https://www.weforum.org>”

## 4. Data Analysis and Results

### 4.1. Descriptive analysis

Descriptive statistics are given in Table 3 below. The average, median, standard deviation (SD) and skewness and kurtosis for all variables in both sets (“Education” and “innovation”) are provided. The highest mean score is for SEER (89.514) and TEER (35.624) while the mean score for other variables is almost the same and with low score. Also, most variables’ distribution is nearly symmetric where the value of skewness near zero except for SEER (-1.212) and PATA (1.458).

**Table 3.** Descriptive statistics for the two sets of the study

Variables	Mean	Median	SD	Skewness
SEER	89.514	92.30	16.813	-1.212
TEER	35.624	33.15	17.477	0.580
QOES	4.027	4.20	1.138	-0.413
QMSE	4.171	4.20	1.142	-0.275
QMOS	4.250	4.30	1.002	-0.207
IAIS	4.358	4.40	1.205	-0.702
LAST	4.230	4.30	0.774	-0.471
EOST	4.048	4.00	0.687	0.109
CFIN	3.817	3.80	0.720	0.124
QSRI	3.617	3.60	0.920	0.109
CSR	3.258	3.10	0.797	0.771
UCRD	3.560	3.60	0.838	0.182
GPAT	3.754	3.70	0.989	0.315
ASAE	4.432	4.40	0.688	-0.376
PATA	4.168	1.70	4.977	1.458

### 4.2. The Correlation Analysis

Figure 1 shows a visualisation of correlation matrix between the two sets, ‘higher education & training’ and ‘innovation’. In the bottom part, it shows the pair scatter plot

with a fitted line, while it shows the (absolute) value of the correlation adding the result of correlation test as stars in the top part. There are strong and significant correlations between the two sets except for one, TEER, which has a weak and insignificance correlation with other variables. The highest correlation is 0.97 (QOES and QMSE), followed by 0.96 (QOES and QMSE and QMSE and QMOS).

This high correlation between the two sets supports making further CCA analysis to find out the interaction between “higher education & training” and “innovation”.

Correlation between the two sets supports making further CCA analysis to find out any interaction between “higher education & training” and “innovation”.

Note: \*\*\*significant at 0.001, \*\*significance at 0.01, \*significance at 0.05  
 Figure 1: Correlation matrix between “higher education & training” and “Innovation”

Figure 1. A visualization of correlation matrix between the two sets

### 4.3. Measuring statistical significance of the CCA

Table 4 shows the canonical correlation (CanR) between the two sets and the p-value (Pr>F) to test if the canonical correlations in the current row and all that follow are zero (Dattalo, 2014). The results of p-values confirm that there are significant four canonical correlations where the p-value is

less than 0.05, therefore, the null hypothesis is rejected. Moreover, the first column, which shows the strength of the relationships, indicates that the strength of the relationship between first pair of canonicals (X<sub>1</sub>,Y<sub>1</sub>) is 0.93, the second pair of canonicals (X<sub>2</sub>,Y<sub>2</sub>) is 0.86, the third pair canonicals (X<sub>3</sub>,Y<sub>3</sub>) is 0.71 and it is 0.50 for the last significant pair of canonicals, (X<sub>4</sub>,Y<sub>4</sub>).

**Table 4.** Assessment of the overall model fit

CanR	LR test stat	approx F	numDF	denDF	(Pr>F)
0.93	0.01	8.82	56	376.89	0.00
0.86	0.08	5.71	42	331.78	0.00
0.71	0.31	3.28	30	286.00	0.00
0.50	0.61	1.93	20	239.75	0.01
0.37	0.81	1.35	12	193.43	0.19
0.25	0.93	0.88	06	148.00	0.51
0.06	1	-	02	-	-

Findings on Table 4 show that there are four significant canonical correlation (p-value < 0.01). Therefore, H 1 and H 2 can be accepted. These results suggest that both sets impact each other and a bidirectional relationship exists. Therefore, the development or change in any set must be seen through the other set. Further analyses have been conducted in the next section to provide more explanations on the nature of the relationship between the two sets and to identify the main players in each set.

#### 4.4. Standardized and Loading Values

To determine the importance of individual variables within each set, we computed the canonical correlation functions as shown in Table V. Then, standardized and loading values were estimated in Tables 6 and 7 as presented below. Table 5 illustrates the estimates of CanR, square of canonical

correlation (CanRSQ), eigen, percent and cumulative of CCA. It is found that the first canonical correlation is about 0.93 that representing 85.9% (canRSQ) of the amount of variance in the first canonical function for the first set accounted for through the first canonical function. In the second set, the estimates of canonical correlation are about 0.86. There is 74.6% of the amount of variance in the second canonical function for the first set accounted for through the second canonical function in the second set and so on. The eigen value represents the shared variance between two canonical functions. There are 57.61% of shared variance for the first canonical functions while it is 27.77% for the second function the shared variance and so on. In total, the first four canonical functions have shared variance of 97.85% (Cumulative).

**Table 5.** The estimate of the canonical correlation functions

No. of functions	CanR	CanRSQ	Eigen	Percent	Cumulative
1	0.927	0.859	6.083	57.61	57.62
2	0.863	0.746	2.931	27.77	85.38
3	0.706	0.498	0.992	09.39	94.78
4	0.495	0.245	0.325	03.08	97.86
5	0.365	0.133	0.154	01.45	99.31
6	0.253	0.064	0.068	00.65	99.96
7	0.062	0.004	0.004	00.04	100.00

The standardized canonical coefficients, which can be used to reflect the relative importance of the original variates in each canonical function (Chew and Dillon, 2014), are presented in Table 6 below. Regardless the sign of the first canonical function

(Xcan1), it can be considered the most important variables in the first set, IAIS (-0.525), followed by QMSE (0.522), then QOES (-0.457), LAST (-0.383), QOMS (-0.186), SEER (-0.146), TEER (0.142) and EOST (0.122).

**Table 6.** Standardized Coefficients for Higher Education & Training (First Set)

Variables	Xcan1	Xcan2	Xcan3	Xcan4
SEER	-0.146	0.143	0.282	-0.081
TEER	0.142	-0.160	-0.326	-0.995
QOES	-0.457	-0.132	0.814	0.021
QMSE	0.522	-0.800	-2.139	1.117
QOMS	-0.186	-0.066	2.621	-0.707
IAIS	-0.525	0.139	-1.609	1.106
LAST	-0.383	-0.582	-0.117	-0.330
EOST	0.122	1.212	0.360	-1.148

Regardless the sign of the first canonical function (Ycan1), it can be considered the most important variable in the second set, QSRI (-0.753), followed by CSRD (0.437),

then UCRD (-0.432), GPAT (-0.218), ASAE (0.066), PATA (0.066) and CFIN (-0.017) as shown in Table 7.

**Table 7.** Standardized coefficients for innovation (second set)

Variables	Ycan1	Ycan2	Ycan3	Ycan4
CFIN	-0.017	-0.139	0.514	-1.259
QSRI	-0.753	0.194	-0.804	0.764
CSRD	0.437	0.482	2.642	1.772
UCRD	-0.432	-0.710	-0.075	-0.434
GPAT	-0.218	1.222	-1.390	-0.737
ASAE	-0.088	-1.098	-0.666	0.297
PATA	0.066	-0.022	-0.280	-1.074

In Table 8, the canonical loadings have been increasingly used to interpret CCA (Härdle and Simar, 2007). They measure the linear correlations between observed variate the h or k sets and the set's canonical function. The square of loading coefficients reflects the variance of the original variate shares with the canonical function. The loading coefficients identify the important contribution of any variate to each canonical function (Huang et al., 2009).

The highest the coefficient, the more important it has in obtaining the canonical function. From Table IIX, regardless the sign of loading coefficients, it can be concluded the most important variables in the first set are IAIS (-0.978), followed by LAST (-0.923), then EOST (-0.912), QOES (-0.884), QOMS (-0.813), QMSE (-0.793), SEER (-0.706) and TEER (-0.003). Results of Table IIX suggest that the most important factors in higher education & training set are the

availability of both the Internet and specialized training centers and the quality of the education system.

**Table 8.** Loading coefficients of higher education & training (first set)

Variables	Xcan1	Xcan2	Xcan3	Xcan4
SEER	-0.706	0.158	-0.239	-0.264
TEER	-0.003	-0.472	-0.380	-0.743
QOES	-0.884	-0.341	0.161	0.013
QMSE	-0.793	-0.494	0.163	0.059
QOMS	-0.813	-0.411	0.343	-0.009
IAIS	-0.978	0.010	-0.131	0.006
LAST	-0.923	-0.239	0.044	-0.145
EOST	-0.912	0.242	0.158	-0.098

Regardless the sign of loading coefficients in the second set, it can be concluded from Table 8 that the most important variables in the second set are QSRI (-0.979), followed by UCRD (-0.962), CSRD (-0.910), GPAT (-0.886), ASAE (-0.829), CFIN (-0.761) and PATA (-0.538). Results of Table 9 suggest

that the most important factors in innovation set are the availability of both specialized scientific research centres and the company's spending on research and development of products, as well as the reliance of scientific research on joint cooperation between the university and industry.

**Table 9.** Loading coefficients of innovation (second set)

Variables	Ycan1	Ycan2	Ycan3	Ycan4
CFIN	-0.761	-0.110	0.458	-0.285
QSRI	-0.979	-0.012	0.095	-0.035
CSRD	-0.910	0.099	0.342	-0.012
UCRD	-0.962	0.006	0.152	-0.038
GPAT	-0.886	0.381	0.017	-0.009
ASAE	-0.829	-0.433	0.029	0.052
PATA	-0.538	-0.101	0.030	-0.605

Figure 2 shows the biplot for the two canonical functions and their variables in terms of loading values. The furthest away these loading values or arrows from origin (0,0), the more impact the variable has on its canonical function. Also, Figure II shows that the impact of the two sets is in the same direction. For the education set ("X"), IAIS has the highest impact followed by EOST while, there is no impact for TEER variable. For the second set, the QSRI has the highest impact followed by UCRD, while PATA has the least impact. One of the most important implications of Figure II is all variables of higher education & training set have a high correlation with first canonical function except for TEER variable. In addition, all variables in innovation set have a high correlation with first canonical function. Such finding supports the impact of each set on the other.

**Figure 2.** Biplot of the two canonical functions and their variables

### 4.5. Cross-loading

To identify the importance of one canonical correlation on another, first, we computed cross-loading in each set (higher education and innovation) in Tables 10 and 11. Second, we measured loading coefficients of each set with the other set canonical function in Tables 10 and 11 as follows. In Table X,

regarding the sign of loading coefficients, it can be considered the most important variables in the first set that have correlated with second set (first canonical function) are IAIS (-0.906), followed by LAST (-0.855), then EOST (-0.845), QOES (-0.820), QOMS (-0.753), QMSE (-0.735), SEER (-0.654) and TEER (-0.003).

**Table 10.** Cross Loading coefficients of the first set with second set canonical function

Variables	Ycan1	Ycan2	Ycan3	Ycan4
SEER	-0.654	0.137	-0.169	-0.131
TEER	-0.003	-0.407	-0.268	-0.368
QOES	-0.820	-0.294	0.113	0.006
QMSE	-0.735	-0.427	0.115	0.029
QOMS	-0.753	-0.355	0.242	-0.005
IAIS	-0.906	0.009	-0.092	0.003
LAST	-0.855	-0.207	0.031	-0.072
EOST	-0.845	0.209	0.111	-0.048

**Table 11.** Cross Loading coefficients for the second set with first set canonical function

Variables	Xcan1	Xcan2	Xcan3	Xcan4
CFIN	-0.705	-0.095	0.323	-0.141
QSRI	-0.908	-0.010	0.067	-0.017
CSRD	-0.843	0.085	0.242	-0.006
UCRD	-0.892	0.005	0.108	-0.019
GPAT	-0.821	0.329	0.012	-0.004
ASAE	-0.768	-0.374	0.021	0.026
PATA	-0.498	-0.087	0.021	-0.300

Regardless the sign of loading coefficients, Table 11 leads to consider that the most

**Table 12.** Redundancy index of the two sets (education & innovation)

	Xcan1	Xcan2	Xcan3	Xcan4	Xcan5	Xcan6	Xcan7	Total
Redundancy index	0.559	0.083	0.025	0.020	0.004	0.002	0	0.695
	Ycan1	Ycan2	Ycan3	Ycan4	Ycan5	Ycan6	Ycan7	
Redundancy index	0.619	0.039	0.026	0.016	0.003	0.002	0	0.706

Table 12 illustrates the redundancy index for the two sets. It can be concluded that the canonical variates for the first set (higher education and training) can explain 69.5% of variance in the original variables for the second set (innovation), especially, the Xcan1 contributes 55.9%. Moreover, the canonical variates for the second set (innovation) explains 70.6% of variance in the original variables for the first set (higher education and training), especially, Ycan1 contributes 61.9%.

#### 4.7. Commonality Analysis

Commonality analysis clarifies the canonical impacts made by using the signals in each

important variables in the second set that correlated with first set (first canonical function) are QSRI (-0.908), followed by UCRD (-0.892), then CSRD (-0.843), GPAT (-0.821), ASAE (-0.768), CFIN (-0.705) and PATA (-0.498).

#### 4.6. Redundancy Analysis

According to Dattalo (2014) and Jendoubi and stimmer (2018), when using the CCA, the redundancy index is used to do the same function of the R-square in regression analysis. This index is the percentage of variance in the original variates of one set that is interpreted by the canonical function of the other set. High redundancy index proposes a high ability to forecast. If there is a clear definition for independent and dependent sets, the researcher may use the redundancy index for independent canonical function in forecasting the variance in the set of original variates in the dependent set.

canonical set to split the variance of canonical functions produced from the other canonical set. These canonical variates can be divided to unique and common impacts. "A canonical commonality unique effect is computed as a squared correlation between the canonical variate for a given canonical set and a variable of interest in the other canonical set. A canonical commonality common effect is computed as a squared correlation between the canonical variate for a given canonical set and the set of variables of interest from the other canonical set after subtracting all unique effects and the variance explained by any other sets of variables" (Nimon et al., 2010).

Table 13 below provides the splitting of higher education & training canonical first function by the variables in the innovation and the splitting of innovation canonical first function by the variables in the higher education & training indicators. The values point out “how much variance can be explained as unique or common by the variables” and the “% total” points out “the percentage of variance that can be illustrated out of the observed canonical impact”. It exposes that the higher education & training variables are explained by variance common to CFIN, QSRI, CSRD, UCRD, GPAT and ASAE (27.63%) of canonical impact, followed by CFIN, QSRI, CSRD, UCRD,

GPAT, ASAE and PATA (21.92%). However, the unique support of these variables is very low. For example, the highest support is attributed to QSRI (0.0339), followed by UCRD (0.0152). Furthermore, it indicates that the innovation variate is explained by variance common to SEER, QOES, QMSE, QOES, QMSE, QOMS, IAIS, LAST, EOST (35.74%) of canonical impact, followed by QOES, QMSE, QOES, QMSE, QOMS, IAIS, LAST, EOST (24.39%) while, the unique support of these variables is very low. For example, the highest support is attributed to IAIS (0.0247), followed by LAST (0.0165).

**Table 13.** Commonality Analysis of education & innovation sets

Splitting of X canonical function				Splitting of Y canonical function				
	Unique	Common	% Total		Unique	Common	% Total	
CFIN (y1)	0.0001	0.4973	0.4974	SEER (x1)	0.0061	0.4215	0.4276	
QSRI (y2)	0.0339	0.7898	0.8237	TEER (x2)	0.0100	-0.100	0.0000	
CSRD (y3)	0.0097	0.7008	0.7105	QOES (x3)	0.0032	0.8885	0.6717	
UCRD (y4)	0.0152	0.77999	0.7951	QMSE (x4)	0.0055	0.5344	0.5399	
GPAT (y5)	0.0067	0.6676	0.6743	QOMS (x5)	0.0018	0.5658	0.5676	
ASAE (y6)	0.0118	0.5883	0.5901	IAIS (x6)	0.0247	0.7966	0.8213	
PATA (y7)	0.0020	0.2462	0.2482	LAST (x7)	0.0165	0.7151	0.7316	
				EOST (x8)	0.0014	0.7128	0.7142	
Highest three commons			% Total	Highest three commons			% Total	
y1, y2, y3, y4, y5 & y6			0.2373	27.63	x1, x3, x4, x5, x6, x7 & x8			0.3069
y1, y2, y3, y4, y5, y6 & y7			0.1882	21.92	x3, x4, x5, x6, x7 & x8			0.2095
y2, y3, y4 & y5			0.1024	11.93	x1, x3, x6, x7 & x8			0.0835

One of the interesting results is obtained by commonality analysis is the explained variance in innovation set is related to common variables instead of one unique variable while, the explained variance in higher education & training set is linked to common variables not a unique variable.

## 5. Conclusion

The study examines the bidirectional relationship between two sets of variables namely, higher education & training with eight indicators and innovation with seven indicators using the canonical correlation analysis through a sample of 12 MEAN

countries. The main result of our study indicates that the canonical variates for the first set (higher education & training) explains 69.5% of variance in the original variables in the second set (innovation). The canonical variates for the second set (innovation) interprets 70.6% of variance in the original variables in the first set (higher education and training). The most important variables in the first set that correlates with second set in the first canonical function are “internet access in schools”, followed by “local availability of specialized training services”, then “extent of staff training, “quality of the education system, “quality of management schools, “quality of math and science education, “secondary education

enrolment rate gross percentage and “Tertiary education enrolment rate gross percentage. The most important variables in the second set that correlates with first set in the first canonical function are “quality of scientific research institutions”, followed by “University-industry collaboration in R&D”, then “company spending on research and development”, “government procurement of advanced technology products”, “availability of scientists and engineers”, “capacity for innovation” and “patent applications”. All variables in higher education & training set have a high correlation with first canonical function except for “tertiary education enrolment rate gross percentage” variable. Further, all variables in innovation set have a high correlation with first canonical function. Our results have confirmed on the bidirectional relationship between higher education & training and innovation. Consequently, H 1 and H 2 are accepted.

Based on the redundancy analysis, the first canonical variate (Xcan1) for the first set (higher education & training) explains 55.5% of variance in the original variables

for the second set (innovation), while all canonical variates explain 69.5%. Also, the canonical variate (Ycan1) for the second set (innovation) explains 61.9% of variance in the original variables for the first set (higher education and training), and in total, all canonicals explain 70.6%. Findings of the commonality analysis shows that the role of quality of management school in explaining the variation in canonical function of innovation (about 36%) in common with “quality of education system”, “quality of math and science”, “internet access”, “training availability and staff training produce”.

The current study, like other studies, have some limitations such as it considers only 12 MEAN countries. Therefore, it is recommended to extend it in a future study through the inclusion of other MENA countries which are ignored in the current study. In addition, the measurement of the variables is based on GCI that is established by WEF. Different measures and other variables can be used in future studies.

## ROAD TO INDUSTRY 5.0: CHALLENGES AND OPPORTUNITIES

**Abstract:** *The application of advanced digital technologies has the greatest potential for innovation in the industry, as demonstrated by Industry 4.0. However, Industry 4.0's technology-centered approach neglects the importance of human impact in its implementation, since this transformation requires new knowledge and skills for engineers and workers alike. The European Commission has introduced the concept of Industry 5.0, which emphasizes the sustainability and resilience of smart manufacturing systems through human-centric production. Thus, Industry 5.0 represents a shift from Industry 4.0, focusing on bringing humans back to the forefront while maintaining the digital agenda to develop human-cyber-physical systems. However, as a new strategy, Industry 5.0 faces a great challenge, where the lack of human resources represents the largest gap. Thus, the present research provides a methodology that supports this strategy shift. In addition, this research addresses the main challenges of Industry 5.0 and provides opportunities for overcoming them based on the developed methodology.*

**Keywords:** *Smart Manufacturing, Industry 5.0, Human-Cyber-Physical Systems (HCPS), Upskilling*

### 1. Introduction

In the last decade, the global hype around digital transformation in the industry was focused on creating smart, connected manufacturing systems based on Industry 4.0 concept, emphasizing the role of Cyber-Physical Systems (CPS) (Qiao, Liu, Ma, & Liu, 2021). However, the CPS environments, in which physical objects and software are closely integrated via the Industrial Internet of Things (IIoT) empowered by Artificial Intelligence (AI), constrict the human impact on manufacturing (Pacaux-Lemoine, Berdal, Enjalbert, & Trentesaux, 2018). Moreover, recently the European Commission (EC) pointed out that humans are still the most valuable asset of every company: they are dexterous, intelligent, flexible, and creative,

and outperform most machines or robots (European Commission, 2019). Thus, it seems that the technology-centered approach of Industry 4.0 has proved improper since the lack of a human impact in the application of Industry 4.0 has been reported (Bajic, Rikalovic, Suzic, & Piuri, 2021; Rikalovic, Suzic, Bajic, & Piuri, 2022). Therefore, it becomes evident that the overall change in the industry has effects that go far beyond technological transformation.

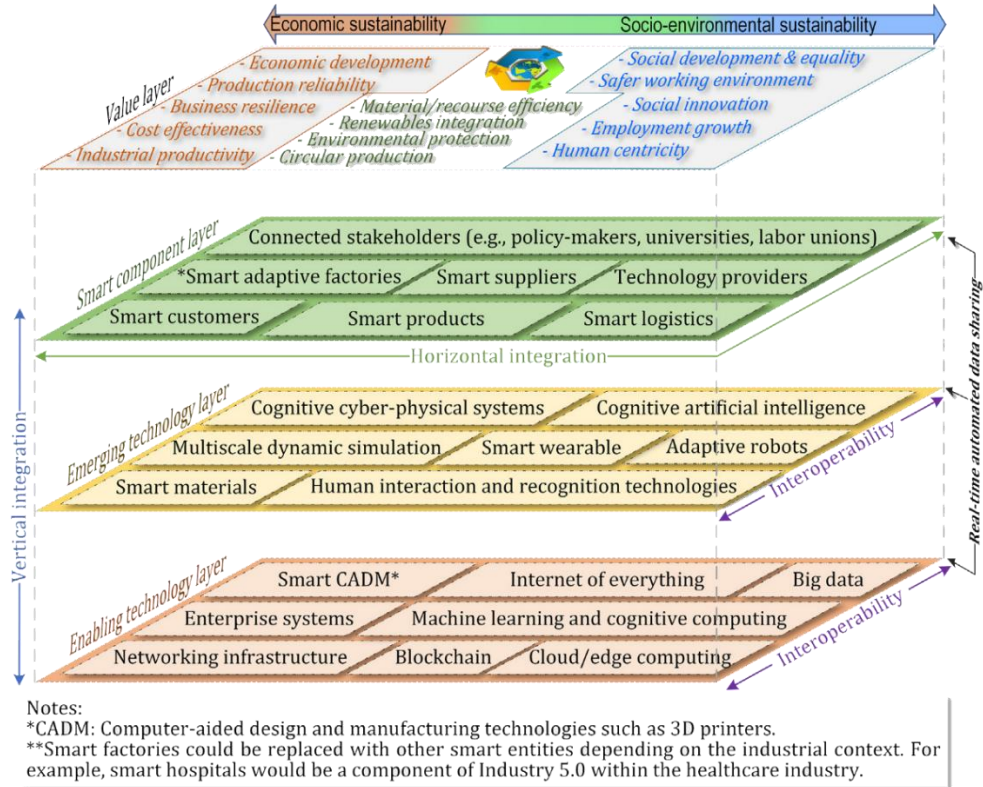

In reply to the paradigm shift, the EC adopted an official document introducing the concept of Industry 5.0 which emphasizes the main role of the research and innovation sector in support of the industry through three core pillars, namely: human-centricity, sustainability, and resilience (European Commission, 2021, 2022). Thus, Industry

---

5.0 puts the human aspect back in the center of manufacturing processes proposing the

development of Human Cyber-Physical Systems (HCPS) (Bajic et al., 2023).

**Figure 1.** The reference model of Industry 5.0 was developed by Ghobakhloo et al., 2022

As a part of the Industry 5.0 concept, the HCPS represents an advanced intelligent system composed of humans— experienced engineers, skilled shop floor workers, and data researchers — implementing the expert domain knowledge in the CPS to achieve a smart manufacturing system by assessing manufacturing data based on AI applications(Bajic et al., 2023; Jabrane & Bousmah, 2021; Maddikunta et al., 2021; Nahavandi, 2019; Zhou, Zhou, Wang, & Zang, 2019).However, this future form of the industry requires new knowledge and skills from both engineers and workers.

Thus, the present research tries to fill the gap and contributes to the existing literature in two ways:1) addresses the main challenges that Industry 5.0 faces and, 2) provides opportunities for overcoming them through the proposed academia–industry collaboration methodology.

The rest of the article is organized as follows. Section 2 provides a theoretical background of Industry 5.0 and HCPS. Section 3 presents the addressed challenges in Industry 5.0, while Section 4proposes the opportunities through developed academia–industry collaboration methodology for overcomingaddressed challenges. Finally, Section 5 derives some conclusions.

## 2. Industry 5.0 and HCPS

The first academic research on the concept of Industry 5.0 dates back to 2016 (Sachsenmeier, 2016) when discussions about the essence of humanity's existence, physical integrity, and relationship with nature were initiated through the emerging field of bionics. After that, many human-oriented initiatives were launched (Demir, Döven, & Sezen, 2019; Nahavandi, 2019; Scanlon, 2018). However, in 2021, the EC adopted an official document presenting Industry 5.0 and emphasizing the main role of the research and innovation sector in supporting industry in its long-term service to humanity (European Commission, 2021).

However, Industry 5.0 is not a new paradigm, but the natural continuation of Industry 4.0. Thus, the transition from Industry 4.0 concept to Industry 5.0 represents a combination of the advantages of a CPS, intelligent machines, and human knowledge, which have a focus on increased productivity, manufacturing resilience, and sustainability (Pizon & Gola, 2023).

Additionally, authors (Ghobakhloo et al., 2022) developed the reference model of Industry 5.0, presented in Figure 1. The reference model describes this phenomenon, explaining its underlying technologies, techno-functional principles, smart components, and values.

Moreover, the official definitions of Industry 5.0 are still abstract ideas generalized from the practices and shortcomings of Industry 4.0, focusing primarily on human aspects (Bajic et al., 2021; Nahavandi, 2019; Rikalovic et al., 2022; Sachsenmeier, 2016), and sustainable and resilient manufacturing processes (European Commission, 2021; Humayun, 2021). Thus, definitions of Industry 5.0 depend on the field of research. In particular, the definition of Industry 5.0, accepted in this research is adapted from (Bajic et al., 2023), and reads as

follows:

"Industry 5.0 represents the concept of transition to sustainable and resilient manufacturing systems focused on human resources (European Commission, 2021, 2022) and driven by advanced technologies, grouped into categories (adapted from (European Commission, 2020)) for:

- individualized human-machine interaction (including robotics with AI and augmented and virtual reality);
- simulation of the production system (including CPS, digital-twins of products, processes, and entire systems); and
- data transmission, storage, and analysis technologies (including IIoT, cybersecurity, big data analytics (BDA), and Edge computing),

to enable the development of HCPS". The Industry 5.0 ecosystem is presented in Figure 2.

Figure 2. Industry 5.0 ecosystem with three main pillars: human-centricity, resilience, and sustainability (adapted from European Commission, 2020)

Human Cyber-Physical Systems are composed of human experts, cyber systems, and physical components to achieve specific manufacturing goals, i.e. flexibility, resilience, and sustainability (Ji et al., 2018; Kim et al., 2022). Noticeably, we were unable to locate a precise definition for HCPS in the relevant literature, nor did we encounter accurate information concerning the term "human". According to some authors (Coronado et al., 2022; Garrido-Hidalgo et al., 2018), "human" in HCPS denotes a shop floor worker who collaborates with machines, i.e., collaborative robots (cobots) (Jabrane & Bousmah, 2021), whereas other authors (Ji et al., 2018; Pathak, Pal, Shrivastava, & Ora, 2019; Zhou et al., 2019) believe that it refers to human knowledge that is implemented within CPS. Nevertheless, no research was found that highlighted the significance of data researchers as a vital connection between CPS and human domain expert knowledge, empowered by AI. To address this inadequacy in the current definitions, we define HCPS as an advanced intelligent system that encompasses humans, such as experienced engineers, skilled shop floor workers, and data researchers, who implement expert knowledge in CPS to achieve intelligent manufacturing systems based on AI and manufacturing big data (Jabrane & Bousmah, 2021; Maddikunta et al., 2021; Nahavandi, 2019; Zhou et al., 2019) presented in Figure 3.

### 3. Industry 5.0 Challenges

As Industry 4.0 failed to fulfill the industry expectation due to managerial and technological challenges (Bajic et al., 2021; Rikalovic et al., 2022), it is considered that Industry 5.0 will overcome those gaps. However, the majority of unsurpassed challenges from Industry 4.0 present issues in Industry 5.0 as well. Thus, the main challenges can be grouped into three

categories referring to the Industry 5.0 pillars, namely: human-centricity, resilience, and sustainability.

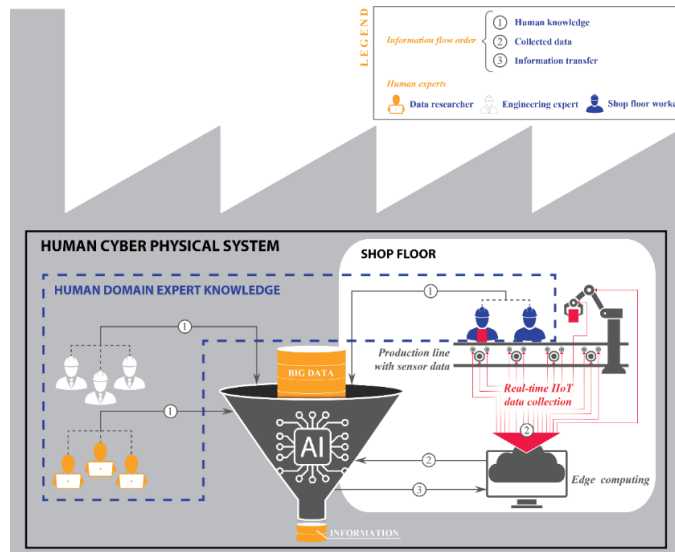

**Human-Centricity.** To achieve human-centric manufacturing, it is essential for every participant in the factory, including both humans and machines, to consistently learn and acquire new knowledge. (Adel, 2022; Gürdür Broo, Kaynak, & Sait, 2022; Lu et al., 2022). Thus, the fundamental prerequisites to Industry 5.0 implementation are related to reskilling and upskilling of experienced engineers and workers. However, the reluctance of workers to embrace change and improve their skills can impede a company's progress in commencing or advancing with the Industry 5.0 implementation (Bajic et al., 2021; Kumar, Bhamu, & Sangwan, 2021).

**Resilience.** To achieve the resilience of manufacturing systems, the most important is to establish trust within HCPS where security presents a challenge in this regard (Adel, 2022; Bajic et al., 2021). The HCPS incorporates a diverse range of cyber technologies (e.g., AI, IIoT, Cloud, Fog and Edge computing, BDA, etc.) that generate, transmit, and handle significant amounts of security and privacy-sensitive data in manufacturing systems, making it susceptible to numerous potential cyber-attacks in the realm of cybersecurity (Wang, Zheng, Yin, Shih, & Wang, 2022). Thus, the integration of AI, IIoT, and automation into HCPS creates security threats, necessitating trusted security measures to protect businesses. The focus of Industry 5.0 applications on information and communication systems leads to stringent security requirements to address security challenges.

**Sustainability.** On the one hand, sustainable development of manufacturing systems seeks the protection of the environment through sustainable products and logistics to approach the zero-waste objective (European Commission, 2022). In addition to waste

prevention, the manufacturing processes must be environmentally friendly (Bajic et al., 2021)—for example, by using renewable resources and digital technologies (Bajic et al., 2023). On the other hand, considering human capital sustainability is essential in the realm of smart manufacturing because

humans possess a considerable amount of knowledge. Moreover, how stakeholders choose to leverage this knowledge can have a profound effect on transitioning the company from CPS into HCPS (Wang et al., 2022).

**Figure 3.** HCPS in Industry 5.0 ecosystem empowered by human domain expert knowledge, AI, and advanced technologies (adapted from Bajic et al., 2023)

## 4. Industry 5.0 Opportunities

In the present section, upon the Industry 5.0 challenges, we derived the opportunities to overcome them. These opportunities are obtained based on the approach of connecting academia and industry to respond to the real needs of manufacturing companies. In addition to the need for digitization to technologically improve companies, a major challenge is also the lack of human resources with adequate skills (Adel, 2022; Bajic et al., 2021; Gürdür Broo et al., 2022; Lu et al., 2022; Wang et al., 2022). Based on these state-of-the-art research papers, the Industry 5.0 opportunities are presented via developed academia-industry collaboration

methodology (Figure 3) consisting of the following phases:

**Phase 1: Industry needs analysis** – represents the collection of relevant information related to Industry 5.0 challenges according to the following steps:

- the industry must determine its specific needs regarding the implementation challenges of the Industry 5.0 concept;
- academia has to do research in the field of implementation challenges of Industry 5.0 that companies have in practice.

The output of this phase will be the aggregate results of all the challenges noted by the industry during the implementation of Industry 5.0. These results are the starting

point for addressing the challenges related to the lack of human resources.

**Phase 2: University/LLL course definition**—represents a response to defined needs based on industry needs. Thus, the response to industry needs will be developed in a two-way direction:

- academia has to develop and improve university courses in accordance to industry needs to teach the next generation of young engineers who will have the skills necessary to develop and implement AI in an HCPS environment of Industry 5.0.
- academia has to develop lifelong learning (LLL) training course for upskilling and reskilling of existing engineers and shop floor workers with AI digital skills and AI-based knowledge to improve:
- lack of Industry 5.0 skilled engineers with a clear vision of digital skills benefits to industry (Bajic et al., 2021),
- engineers' resistance to knowledge upgrades (Kumar et al., 2021),
- engineer acceptance of AI in manufacturing processes (Angulo, Chacón, & Ponsa, 2023; Nahavandi, 2019).

The results of this phase will be developed courses for students/engineers based on theoretical and practical AI knowledge for implementation of HCPS in Industry 5.0.

**Phase 3: Industry 5.0 engineers**—represents the implementation of developed University/LLL courses and attendance of students/engineers/shop floor workers in relevant courses for the practical application of AI HCPS. Thus, the upskilling should be done based on academia and industry collaboration to design the Industry 5.0 labs for practical education and simulation of AI-based manufacturing for both students and engineers.

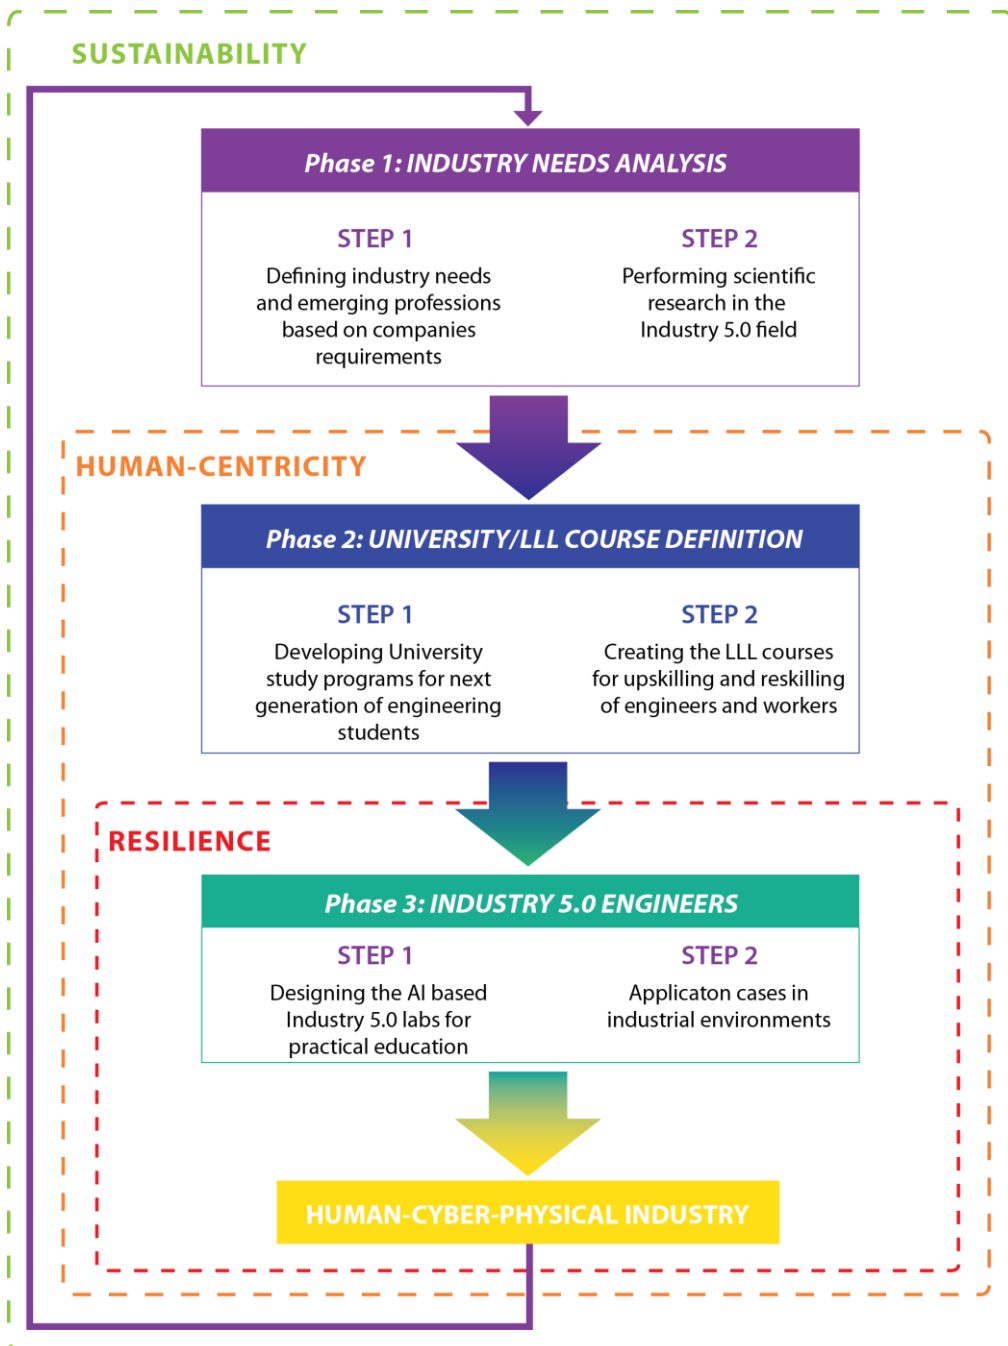

The results of this phase will be trained students and engineers with AI knowledge for practical application of Industry 5.0. The first goal of this phase will be training students in the development and use of AI to improve the industry in the direction of HCPS in Industry 5.0. The second goal will be the training of engineers and shop floor workers employed in the industry in the direction of Industry 5.0 so that they can practically and independently apply AI tools to solve manufacturing problems.

The proposed methodology represents a resilient, human-oriented, and sustainable concept for overcoming Industry 5.0 challenges, whereby:

- human-centricity is reflected in the cooperation between academia and industry to transfer and implement state-of-the-art knowledge in the field of AI with a focus on Industry 5.0, where AI will enable increased levels of automation and human interaction in HCPS environments,
- resilience is reflected in the generation of knowledge within the industry itself, where a new generation of engineers would be able to independently apply and develop AI models,
- sustainability is reflected in the circular process of continuous improvement of the industry by applying AI skills.

The developed methodology provides opportunities for future academia and industry collaborations. This collaboration will ensure the adaptation of existing needs, both in the industry and academia, for providing knowledge and skills to existing engineers working or students that can work in the future in the companies, able to sustain industry to obtain and apply AI-based to the HCPS solutions.

**Figure 3.** HCPS inIndustry 5.0 ecosystem empowered by human domain expert knowledge, AI, and advanced technologies (adapted from Bajic et al., 2023)

## 5. Conclusion

Industry 5.0 represents a shift towards a more human-centric, sustainable, and resilient approach to achieving HCPS production. However, achieving these goals presents several challenges that must be overcome. One major challenge is the need to ensure that human engineers and workers remain at the center of the manufacturing process, with advanced technologies, such as AI, IIoT, BDA, and automation, being used to augment rather than replace workers. This will require a focus on upskilling and reskilling workers, with an accent on designing workplaces that prioritize workers' safety and well-being.

Another challenge is the need to design a resilient manufacturing system in Industry 5.0 with a focus on cybersecurity. Cybersecurity refers to a company's ability to anticipate, withstand, and recover from cyberattacks. It requires a comprehensive strategy of continuous improvement that includes proactive measures, and incident response plans. The goal of minimizing the

impact of security incidents on a company can be achieved by using advanced technology (e.g., Edge computing) to ensure that knowledge and data flow will stay within the manufacturing company limiting external intrusions into the system.

Finally, achieving sustainability in the manufacturing industry, with a focus on reducing environmental impacts such as greenhouse gas emissions, waste, and resource depletion. This will require the use of new green technologies, e.g., AI and BDA, that are more efficient. The use of AI and BDA can minimize waste and maximize productivity.

Thus, to solve all of these Industry 5.0 challenges in HPS environments, this research provides the methodology for establishing the collaboration between academia and industry, to develop strategies (i.e., focusing on knowledge upgrading) that can ensure the long-term viability of industrial manufacturing in an uncertain and rapidly changing world.

## QUALITY 5.0: FROM CHALLENGES TO REALITY

**Abstract:** A world is in process of rapid changing in all areas of living. In all of them exists old and new problems with urgent needs for solving. Transition from Industry 3.0 to Industry 4.0 changed view on industry in 21st century and also there are answers on challenges based on Quality 3.0 and Quality 4.0 concept. In last ten years is developed concept of Japan's „Society 5.0“ which needs Quality 5.0 concept. This is main motive for researching possibility for transition quality into Quality 5.0.

In the paper are presented basic information about Industry 4.0 and Quality 4.0 based on new challenges in 21st century. Based on literature and own research is defined concept of Quality 5.0 and ways of transition to Quality 5.0, especially in transition countries as Serbia in next 30 years. The first analysis pointed out that it is possible with using smart technologies, smart leadership, smart people and other smart „things“ for achieving smart/integrated quality, quality of life, resilience and all human-centric activities.

**Keywords:** Society 5.0, Quality 5.0, Quality of Life, Resilience, Serbia.

### 1. Introduction

The trend in 21st century is to establish smart society in which is included more than 27 smart components. For this research are interesting smart industry (Industry 4.0) and smart quality (Quality 4.0). This process is located in all technology advanced states, but also in some states with big Intellectual Capital (IC). These concepts are defined for each components of smart society. There is problem of integration and including human being and problems of sustainability, quality of life, resilience etc. These are challenges for developing concept of Quality 5.0 dedicated to „Society 5.0“ development ed in Japan. It is great transition with for fundamental themes (CSTI, 2019):

- creating new values for industry development in future and social transformation,
- reorganising economic and social challenges,
- higher support for science,
- technology and innovation (STI), and
- establishing sistem cycles of human resurces, knowledge and capacity for innovation.

For its realization is necessary investment in R&D minimum 4% of GDP from private and public sector, from state government minimum 1 percent. With introduction „Society 5.0“ in Japan expect enhancing GDP circa 3.3%. The goal of „Society 5.0“ is to achieve economic rise/wellbeing and in

---

Corresponding author: Slavko Arsovski  
Email: [cqm@kg.ac.rs](mailto:cqm@kg.ac.rs)

same time overlapping social challenges and in total prosperity of global society.

According Tompston N. (2014) are recognised four waves of changes until year 2050., i.e. :

1. first wave (2010-2020) with slow development of technologies and first introduction of smart solutions,
2. second wave (2020-2030) with development strategy innovation related to RFID, telemetrics, integration, etc.,
3. third wave (2030-2040) with self-assembly, masive 3D printing, self purchasing, etc.,
4. fourth wave (2040-2050) with paradigm of confidence, supported by advanced robotic and AI, autonomuos vehices, sensing material

In smart society is higher role of ethical and well-being aspects. Etical government realizes through: (1) impact of regulatives, (2) regulation of collective actions, (3) building/modernising existing regulation, (4) anticipating strenght of transformation of collective adaptive systems (ACS), (5) balancing government decisions, (6) decising adaptive government, etc. Based on Deloitte (2018) are emphasized challenges in smart cities which need quality answers in following areas:

- smart economy,
- smart environment,
- smart living,
- smart mobility,
- smart quality and safety and
- smart education.

Transition of concept Industry 4.0 to Society 5.0 has impact on planning big social transformation in Japan with destroying five walls related to:

- ministries/agencies,
- legal system,
- technology,
- human resurces and

- social acceptance.

A transition from Industry 4.0 to Industry 5.0 is practicaly transformation of digital manufacturing to digital society (Skobelev P.O., Borovik S.Y., 2017) with convergence of science and technologies in society 5.0 from technology to society.

A concept of enterprise value management defined for smart enterprise in Industry 4.0 could be make broader for Society 5.0 and Quality 5.0 (Fujitsu Consalting, 2002).

According Kearney A.T. (2017) value dimensions from converging technologicis have levels:

1. value for the factory,
2. value to the firm (enterprise),
3. value to the industry,
4. value to society, and
5. value to the individual.

In all of the levels are included elements of Quality 4.0 (level 1, 2 and 3) and Quality 5.0 (level 4 and 5).

Kueper D. et al. (2019) analyzed Quality 4.0 and concluded that cca 63% companies had not decision or plan for it, but only 16% had some form of implementation. The challenges of implementation were: (1) cost of quality check, (2) first-pass yeald, (3) defect rate, (4) rework rate, (5) on-time delivery, (6) customer satisfaction, (7) waranty claims, and (8) product-related complaints. All challenges are base for Quality 4.0 and Quality 5.0, also on levels 1 and 2 in value creation.

A Quality 5.0 concept is connected with Industry 5.0 (Nahavandi S., 2019) with advanced technologies: (1) networked sensor data interoperability, (2) multiscale dynamic modeling and simulation: digital twins, (3) shopflor trackers, (4) virtual training, (5) intelligent autonomous systems, and (6) advances in sensing technologies and machine cognition.

In Industry 5.0 is appropriate to use concept of Lean Innovation because is based on value management (Ozkeser B., 2018). Relations among Quality management in the 21st Century and Industry 4.0 are analyzed in Gunasekaran A., Subramanian N., Ngai E. (2018).

In this research are emphasized following quality topics for Industry 4.0:

1. economic aspects,
2. decision models in quality,
3. business models,
4. human aspects in quality (including leadership),
5. technological aspects in quality.

Authors conclude that is necessary to make alignment between human aspects and technology revolution in quality management.

A concept of Quality 5.0 is connected with concept Society 5.0. According CSTI (2019); Filip, D. et al. (2014); Nakićević N. et al. (2019) and Smith J. et al. (2018) are defined fundament goals:

- goal 1: Leave N<sub>0</sub> Person Behind,
- goal 2: Empower Users through Good Digital Identities,
- goal 3: Make Business Work for People,
- goal 4: Keep Everyone Safe and Secure,
- goal 5: Build new rules for a new game,
- goal 6: Broke through the data barriere

Author concluded that start is beginning.

## 2. Challenges in 21<sup>st</sup> century

In 21st century are expecting a lot of challenges (Klein F., Bansal M., Wohlers J., 2017). In this study are emphasized the megatrends of tomorrow's world divided into five categories:

- society,
- technology,

- environment,
- economy, and
- politics.

For Society 5.0 and Quality 5.0 are specially highlined:

- artificial intelligence,
- augmented reality,
- digitalization,
- IoT,
- climate change,
- concentration on wealth,
- demand for customization,
- environmental awareness,
- focus on transparency,
- globalization,
- partnership models,
- resource scarcity,
- sharing economy,
- social media,
- industry consolidation,
- urbanization,
- geospatial technology,
- terrorism defence, etc.

A way from Industry 4.0 to Society 5.0 and Quality 5.0 needs a big societal transformation, with challenges to avoid or override barriers related to:

- ministries and agencies,
- legal system,
- technologies,
- human resources,
- aging of populations, etc.

The challenges are related to:

- data availability, security and accuracy,
- technology,
- competences,
- openness,
- ecosystem,
- project solutions,
- security of realized system.

A big challenge is related to citizen, i.e. happiness or quality of life in modern society (Kanazawa S., Li N., 2015). It is now element of concept Quality 5.0.

In Gladden M. (2019) is analyzed „Society 5.0“ from aspect of antropological posthumanized societies in future. In this study is asked answer on questions:

1. how different types of human and non-human members can collaborate, besides difference among them,
2. how can make concept dynamics of members of „Society 5.0“, and
3. in which aspects are different members of „Society 5.0“ from societies 1.0 to 4.0.

At the end are stated three questions:

1. does exists samting real new in concept 5.0? Answer: is positive.
2. does the paradigm Society 5.0 could be apploed aut from Japan? Could with some adaptations.
3. How have to collaborate all stakeholders in purpose of realization of Society 5.0? Answer:

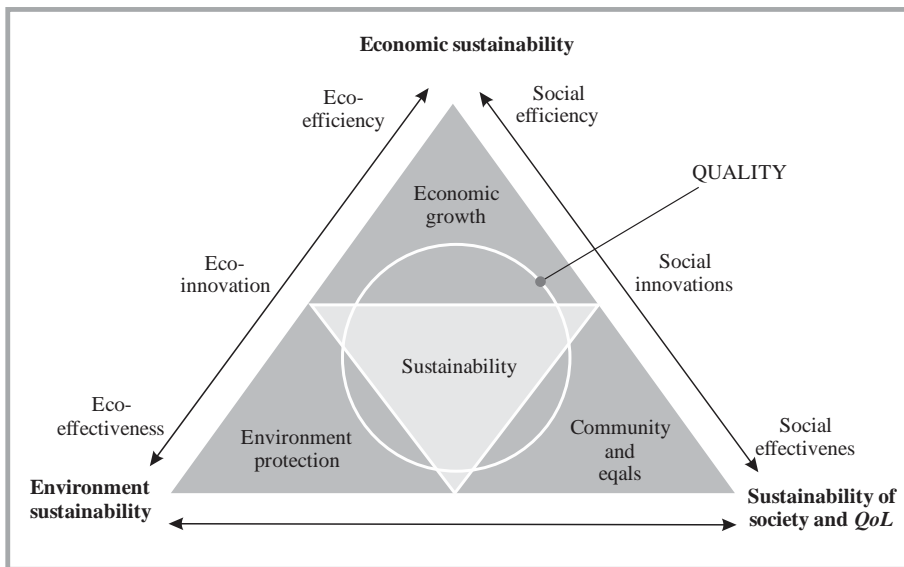

on theoretical and organizational level.

As extension of Society 5.0 is developed concept „Living Laboratories“ and „Living Services“ (Fjord, 2015) based on IoT in broad applying and close relations among people, machines and environment.

In Society 5.0 a quality has higher impact and „glue“ role. A complexity of these reguests, challenges, needs to develop a new paradigm: Quality 5.0, what is explained in next chapters.

### 3. Concept of quality 5.0

Quality 5.0 concept in Society 5.0 is directly related with sustainability, sustainable digital innovation, digital culture, social innovations, quality of life. In figure 1 is presuted quality in context of sustainability.

**Figure 1.** Quality in context of sustainability

In this model quality is incorporated in all elements of Society 5.0. It is enabler of economic growth, sustainability,

environment protection, community and equals of peoples, and sustainability of society and quality of life (QoL).

It is defined for extension of existing situation (Quality 3.0/Quality 4.0 in first phase) and creating new reality in future (second phase). On figure 2 is presented structure of concept Quality 5.0 and relations with environment.

This concept started from a quality practice (on the bottom) divided with different areas, as industry, education, food, etc. On higher

level is quality science with different themas. Each thema has different depth of development and introduction in practice. On higher levels are Quality 4.0 and Quality 5.0 connects with mutual relationships, and also relationship with presented entities in social and spiritual cyber area (environment).

**Figure 2.** Levels to achieving a Quality 5.0

A Quality 5.0 consists from different areas (1 – N). Each area of quality has own depth. Through relation R19 and R20 is performed correspondence with socially 4.0/5.0 as present level of development. On the highest level in the model is Quality 5.0 which has inputs through relations:

- R3: new technological, social and other solutions,
- R21: research and development of intelligent technologies based on knowledge and spirituality,
- R19: common elements from Society 4.0/5.0, and
- R15, R18: new themas from paradigm „Quality Science“ (on second level).

On second level is emphasized:

- Quality science and
- Society /quality 4.0/5.0.

Each relation in this level with elements in other levels has own content, related entities and in total own antology. An egsample, R24 represent impact and results of research of concios fields on innovativeness or a.e. sustomer decision.

According Jacob D. (2017) LNS research a Quality 4.0 has 11axes, i.e.:

1. data,
2. analitics,
3. connectivity,
4. collaboration,
5. application development,
6. scalability,
7. management systems,
8. compliance,
9. culture,
10. leadership, and
11. competency.

Each axis has own sub-elements.

She highlined scientific method versus data science. On this approach Quality 4.0 is defined as CIA:

- C (Connectedness),
- I (Intelligence) and
- A (Automation).

in appropriate Quality 4.0 Ecosystem. In center of this system are Neural Networks and Deep Learning. Some elements of her model of Quality 4.0 are oriented to excitement (drive out fear, build safety and quality culture, and find meaning and purpose) and on this way is connected with Quality 5.0 concept.

Mourtzis D. et al. (2019) emphasized aspects of internal complexity and ICT based relations in digitalized manufacturing system (Cyber-Physical Systems) of Industry 4.0.

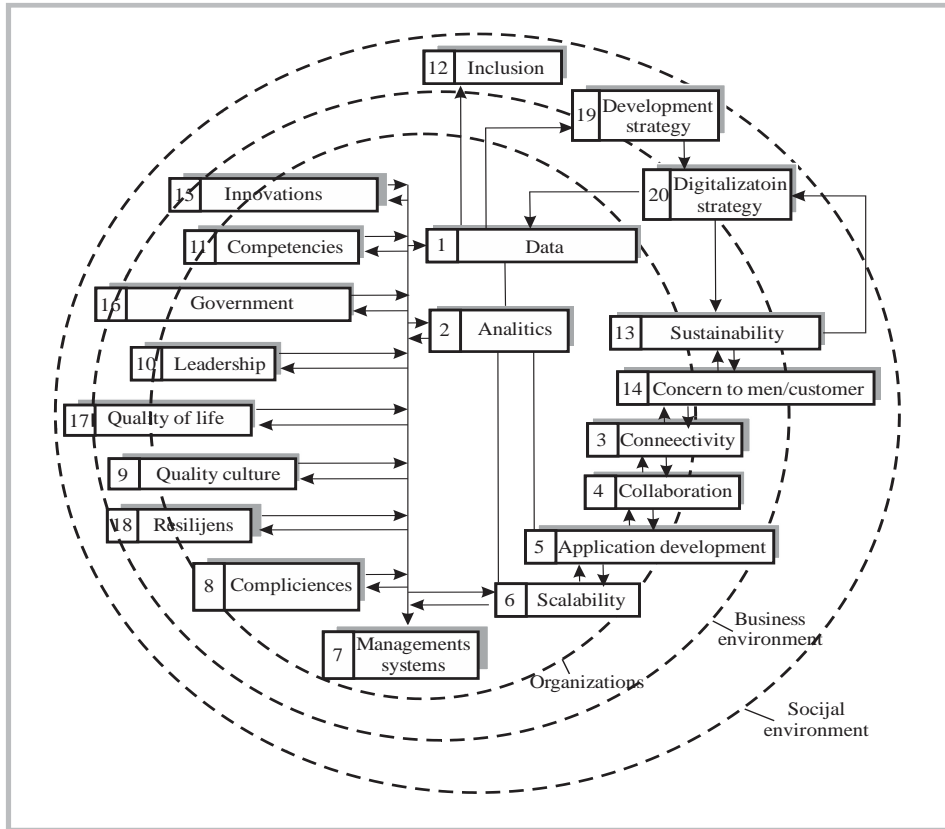

Integration of Quality 4.0 and Quality 5.0 concepts are presented in figure 3.

In purpose to make concept Quaality 5.0 is necessary to integrate Quality 4.0 with external entities. Besides previos described variables (1-11) in Quality 4.0 model and (12-18) in Quality model, in integrated Quality 5.0 (figure 4) are included variables (Arsovski S., 2019):

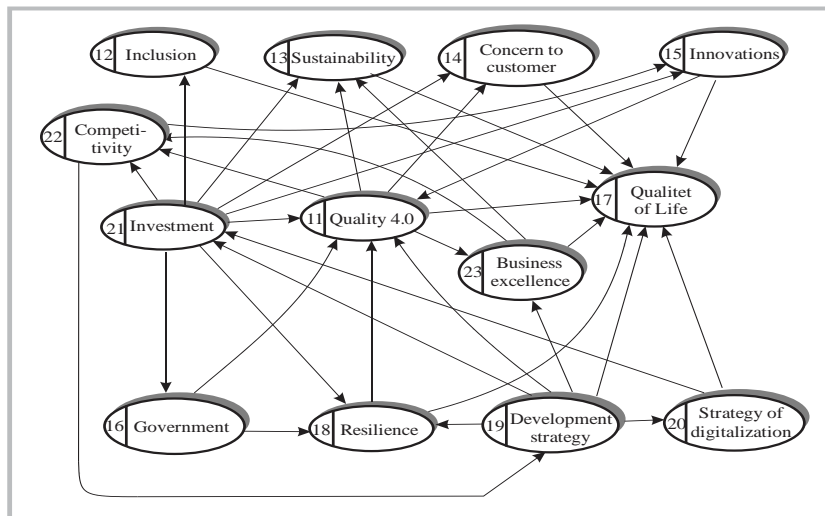

- V19 – strategy of development,
- V20 – strategy of digitalization,
- V21 – level of investment in Quality 5.0,
- V22 – competitiveness level, and
- V23 – level of business excellence.

There are a lot of relations and problem in model testing are data (present low level), its reliability in future and appropriate methods. Proposed solution is to concept national project „Quality 5.0“ to find optimal strategy to transit from existing Quality 2.0/3.0 to Quality 4.0/5.0.

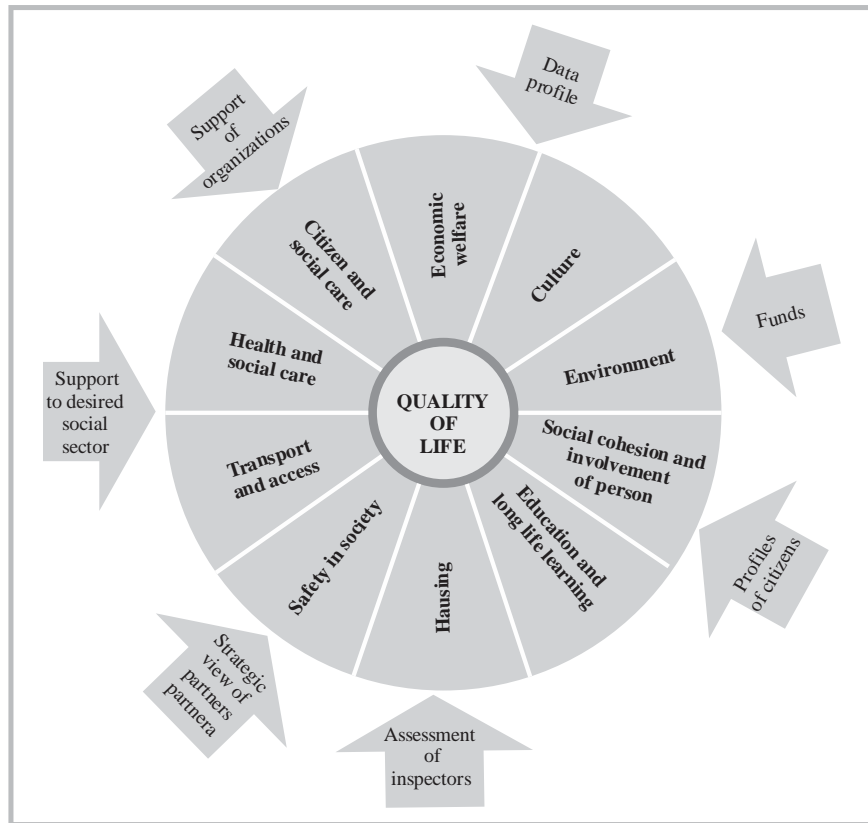

Quality 5.0 is very closely connected to Quality of Life (figure 5).

**Figure 3.** Integration Quality 4.0/Quality 5.0

**Figure 4.** Integrated Quality 5.0 model

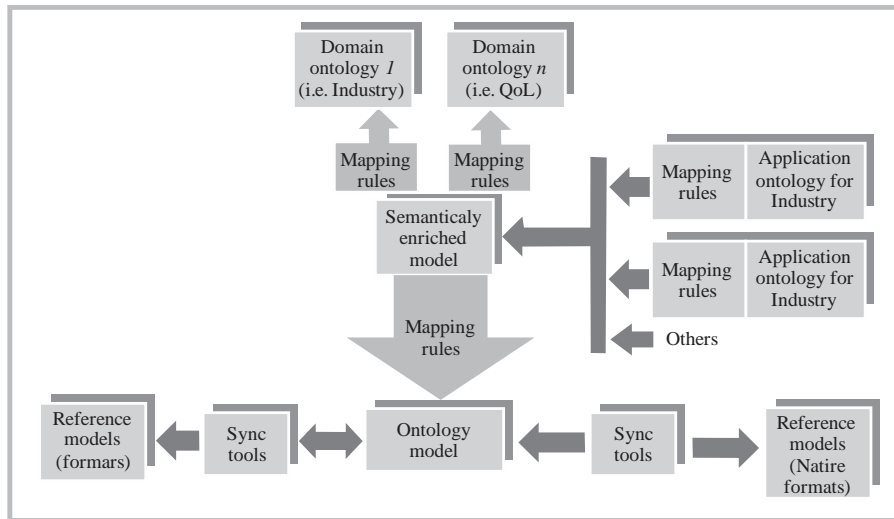

**Figure 5.** Impacts on Quality of Life (QoL)

After analysis elements of Quality 5.0 concept is possible to define appropriate ontology (figure 6), based on Zdravković M. et al. (2011). Each of impacts has different mutual collision. Because that on level of local community is necessary to develop strategy of sustainable community (Arsovski S., 2019).

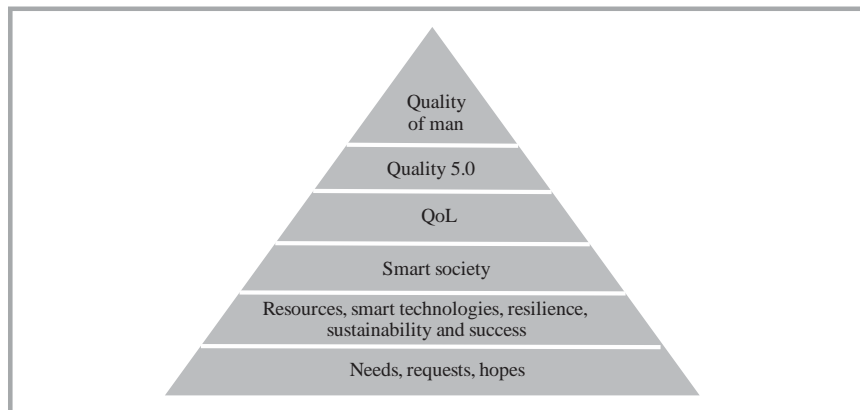

For this framework are crucial domain ontologies and mapping rules, tools and application ontologies for different elements of Quality 5.0, presented through hierarchical model (figure 7).

On the top of pyramid is quality of person, as highest goal of our civilisation. A Quality 5.0 is enabler together with QoL. On lower level is smart society (platinum Society 5.0) based on resources, smart technologies, resilience, sustainability and success of each component of smart society. A base for all are needs, requests and hopes of people.

On this way, this pyramidal model with quality of men is similar with Japan's pyramid of Total Quality Management with men on the top.

**Figure 6.** Framework for semantic environment of reference models for Quality 5.0

**Figure 7.** From human needs to Quality 5.0 and Quality of men

#### 4. Ways to realization of quality 5.0 in Serbia

According to figure 8 the level of quality in Serbia is between low and middle.

This assessment is provided using Delphy method with 15 experts. The average level in Serbia is approximately cca 30% i.e. mixed Quality 2.0, Quality 3.0 and in some cases Quality 4.0. Based on Japan's vision 2050 the process to „Platinum Society“ 2050 with Quality 5.0 consumes a lot of time (cca 30

years) and it is very expensive.

Each component of smart society needs very high investment in purpose to achieve level near assessment 10. For transition society to „Platinum Society 2050“ and Quality 5.0 is necessary in first step to develop vision and strategy for this giga projects which need more than billions of dollars, depend on priorities and constraints for each state. In this moment with respecting cost/benefit analysis is possible to find priorities with best ratio and invest in it (figure 9).

Figure 8. Level of development and introducing elements of Quality 4.0/5.0 in Serbia

Figure 9. Results of benefit/cost analysis (CBA)

The Quality 5.0 concept is closed with Smart Society (Platinum Society) which also needs huge investment in all 27 areas (Arsovski S., 2020, Smart region of Eastern Serbia, ALPEN TEKIJ, Kragujevac, in Serbia).

Dinamics of introducing new development solutions related to Quality 5.0 and Platinum Society in Serbia is presented in figure 10, as first approximation.

**Figure 10.** Investment in Quality 5.0 and Platinum Society in Serbia

In this approximation for Quality 5.0 according priorities is needs to invest in quality in all 27 components of smart society in Serbia. For this study is not included risks in this long period, especially related to natural, ecological, political, health, and other hazards.

## 5. Conclusion

A Quality 5.0 concept is now reality but it is

partly developed and introduced. Specially for Serbia, it is problem because relative small level of quality and constraints in investments, knowledge and generally human factor. Author proposes strategy according Japan's long range strategy, with close collaboration all stakeholders, especially government, investors, local government, business sector, universities et others.

## A CONCEPTUAL REVIEW OF DIGITAL TWIN-BASED BUSINESS ECOSYSTEMS IN SUPPLY CHAIN PLANNING

**Abstract:** *In Today's fickle environment, supply chain management has become increasingly delicate and complex. In this context, a well-performed supply chain requires incorporating digitalization into supply chain networks. To fill this gap, the proposed paper aims to provide a better comprehension of prerequisites required when developing a digital twin in manufacturing supply chains, as well as the benefits and service business growth opportunities that are created for different companies by participating in a digital twin business ecosystem, and further the expected benefits for the entire ecosystem. Findings revealed that digital twins in the manufacturing supply chains are changing the way they do business. They offer a range of opportunities to facilitate collaborative environments, data-driven decisions and make business processes more robust. Finally, the paper aims to help academicians and practitioners to have good insight and overview of digital twins into supply chain planning activities and also it can provide insights for businesses regarding the use of digital twins in supply chain planning, helping them to improve their operations and gain a competitive advantage.*

**Keywords:** *Digital twin business- innovation ecosystem- supply chain planning- manufacturing supply chain*

### 1. Introduction

Computerized twins give a few modern openings for item and benefit advancements for fabricating companies, and hence, this innovation is anticipated to alter the product-service offerings of fabricating companies (Tao et al., 2019). Besides, computerized twins are gathered to form modern commerce opportunities for a few companies inside the whole fabricating environment (Oubrahim, Sefiani, & Happonen, 2023). In expansion to the expanded product-service offerings of fabricating companies, modern databased benefit businesses are assumed to seem in, for illustration, arranging, extend

administration, reenactment modeling, visualization, control frameworks, robotization, and information analytics administrations. However, the application ranges and benefit trade concepts related to advanced twins are still within the investigation stage (Ivanov & Dolgui, 2021; Oubrahim, Sefiani, & Happonen, 2022). The later writing surveys on advanced trade biological systems within the fabricating industry, (Huikkola, Kohtamäki, & Ylimäki, 2022) have examined that there exists a require for more empirical-level understanding around the operations of advanced commerce biological systems such that they can dodge both the benefit and digitalization catch 22s. In expansion to

advanced commerce biological systems, the benefit trade and servitization among the fabricating organizations have been investigated as of late. Indeed, in spite of the fact that there exists an understanding on both advanced trade biological systems and benefit commerce in a computerized trade environment, (Jovanovic, Sjödin, & Parida, 2022) have stated that the inquire about on industrial digital stages is still early. Since all the understanding from B2C setting isn't transferrable to B2B setting and to mechanical advanced stages. (Park et al., 2019) have argued that, for this reason, scholars should pay more consideration to exploring the early stages of the advancement of stage biological systems, for illustration, to get it how stage administration components advance. Concurring to (Huikkola et al., 2022), there's, for occasion, a got to get it how the parts of administrators alter when a conventional advanced arrangement utilizer needs to gotten to be a framework supplier and bad habit versa.

## **2. Background**

### **2.1. Digital twin**

An advanced twin may be a virtual show and comprehensive portrayal of the framework utilized to get it the execution parameters, improve forms, and viably improve value-added activities (Park et al., 2019).

An advanced twin may be a computerized partner of the physical frameworks based on a reenactment that bargains with plan frameworks and optimizes them for moved forward productivity (Guo, Zhao, Sun, & Zhang, 2019). Computerized twin improvement has significant potential in feasible fabricating operations since of its data-rich environment that encourage real-time checking, recreation, and forecast of fabricating forms (Cheng, Zhang, Tao, & Juang, 2020; Oubrahim, Sefiani,

Quattrociochi, & Savastano, 2022). Numerous fabricating organizations have mechanized their generation lines utilizing mechanical frameworks and IoT-based innovations, producing advanced data.

The computerized twin mimics the fabricating environment based on the collected data and makes a difference the proprietor choose between the accessible activities for expanded productivity, superior precision, and economies of scale (Alam & El Saddik, 2017). Cyber physical frameworks have played a basic part in numerous up and coming advances with the improvement of real-time detecting, progressed control, counterfeit insights, and service-oriented fabricating. Savvy fabricating, combined with cyber physical framework improvement, has cleared the street for advanced twin innovation to supply sufficient determination to arrange between the physical world and the virtual world (Alam & El Saddik, 2017; Oubrahim, Sefiani, Happonen, & Savastano, 2022). The interoperability between these developing advances comes about in critical potential for the improvement of compelling stages and applications to screen and control the fabricating frameworks, changing them into maintainable fabricating frameworks (Ahidar, Sarsri, & Sefiani, 2019; Cai, Starly, Cohen, & Lee, 2017).

The existing writing demonstrated that organizations are considered fruitful on the off chance that they can deliver high-quality items assembly client needs and desires with moo fabricating and supply chain costs (Leng et al., 2020). An advanced twin can control generation forms in reaction to the changing showcase needs with tall precision and nimbleness. Computerized twin systems have considered one or more fabricating offices with the center of creating free customized applications, but they need a center on creating a advanced twin as a center mechanical component of the whole framework (Leng et al., 2020). The

computerized change plan of numerous organizations requires overhauls in existing fabricating frameworks to shrewd and brilliantly maintainable fabricating frameworks. A digital supply chain twin is utilized for progressed supply chain modeling based on prescriptive analytics that works in real-time and can decide the correct remedial activity supporting supply chain optimization. The potential of the advanced twin within the supply chains and later advancements in rising advances, such as added substance fabricating, BDA, and IoT, request a survey of existing writing to get it computerized twin components, applications, and challenges.

The advanced twin, combined with the control of huge information analytics, fake insights, and interconnected IoT frameworks, has the potential to open covered up esteem for organizational decision-making (Lu & Xu, 2019). Computerized twin proprietors can foresee operational disappointments, make strides item quality, and diminish downtime (Tao et al., 2018a). The innovation effectively employs nonstop optimization frameworks, which bolsters consolidating the framework and handle parameters amid the generation cycle [15].

Advanced twin innovation offers three noteworthy points of interest. To begin with, it permits existing generation frameworks, forms, and components to be coordinates and made congruous utilizing little gadgets like sensors and application program. Moment, it makes a difference increment efficiency by diminishing blunders and applying predictive maintenance to diminish breaking down. At long last, the generation information of computerized twins is put away within the framework and are utilized for handle optimizations. Simchenko et al. (2020) recommended utilizing computerized twins to map exercises over the whole supply chain. As before long as client orders are entered into the framework, the arrange

points of interest and related exchanges can be captured by the advanced supply chain twin, empowering real-time simulation and decision-making. For case, in case any delays happen within the supply chain due to machine breakdown or supply delays, this data can be sent to the advanced supply chain twin utilizing developing advances such as mechanical IoT gadgets, cloud computing, and enormous information analytics. In this manner, it is fundamental to survey how distinctive Industry 4.0 advances can meet supply chain needs when considering the arrangement of advanced supply chain twin.

The literature uncovered the utilize of different Industry 4.0 advances that are utilized within the computerized supply chain twin design. We recognized IoT, recreation modeling, cyber physical frameworks, machine learning, and fake insights as up-and-coming innovations that can play a noteworthy part in creating advanced supply chain twins.

## 2.2. Digital twin business ecosystems in manufacturing

In later ponders, the part of advanced twins in shrewdly fabricating and related stages has produced a extraordinary bargain of intrigued. He and Bai (2020) [16] propose a nitty gritty system for computerized twin-driven feasible fabricating. They highlight the preferences of advanced twins for expanding insights and maintainability at diverse layers of the generation stage, such as fabricating gear, frameworks, and administrations (He and Bai, Li et al, 2020) contend that advanced twins can successfully interface the gadget layer and arrange layer in fabricating frameworks, hence they play a more successful part in all esteem joins. By coordination divided advanced data, companies can be given with a comprehensive see on, for illustration, items, fabricating, supply chain, client encounter,

and productivity. Be that as it may, fair utilizing computerized twins to upgrade trade victory in fabricating stages isn't sufficient. It is similarly vital to coordinate these empowering advances with the real needs of clients and clients Hannola et al. 2021. Li et al. 2020) have also recommended that companies ought to change from company-centered to user-centered substances to move forward their productivity and adequacy and client involvement. This change is as of now on its way in numerous fabricating companies, which are moving center from a product-centric approach to combined item and benefit offerings, called servitization. Adjusting between the benefit needs of clients and income goals has ended up a central source of competitiveness within the fabricating division. (Cenamor, Rönnerberg Sjödin, & Parida, 2017) have recommended that a stage approach may encourage both customization and operational proficiency by leveraging the esteem of advanced advances to overcome the so-called benefit conundrum. One striking contention in their think about is that a stage approach requests that companies distinguish and characterize modern parts. They too contend that the engineering and stage parts of servitized manufacturers to reinforce understanding of how to form fruitful environments within the fabricating division; all performing artists included ought to know their part and have a unflinching commitment to work collaboratively to use the esteem of shared data (Tao et al., 2019). The selection of modern sorts of parts and endeavors for esteem cocreation and shared interface are among the key prerequisites for an ecosystem-based trade (Oubrahim, Sefiani, Happonen, et al., 2022). (Meierhofer, West, Rapaccini, & Barbieri, 2020) have come to comparable conclusions after analyzing shrewdly mechanical administrations from the angle of their esteem recommendation. They state that producers got to forsake the

part of esteem maker and instep adopt the considering demonstrate of esteem cocreation through client interaction. As famous, advanced twins are a momentous enabler for the development of a benefit trade within the fabricating sector. However, each participating on-screen character will have different jobs and encounter distinctive torments and picks up, each of which is subordinate on the circumstance in address. The so-called commerce system, that's, the requirements of the performing artists within the biological system and the esteem in utilize, ought to be modeled to begin with. As it were at that point will applying an advanced twin arrangement to supply the esteem in utilize be considered as a way of coordinating with 'the actor's problem'. This cultivates cocreation of esteem between distinctive on-screen characters, such as suppliers and clients (Meierhofer et al., 2020). Be that as it may, since ecosystem-based considering is still or maybe a modern marvel in companies, they regularly battle with embracing the prerequisites of an ecosystem-based commerce. A ponder by (Kokkonen et al., 2022) on DBEs found that companies regularly recognize the potential of unused shapes of esteem cocreation, but they as a rule endure from finding ways to arrange participation, and hence, they battle at adapting with interconnectivity, interoperability, and competing interface. In this paper, it is contended that the complementarity of distinctive companies' offerings isn't a prerequisite but or maybe ought to be developed in a shared advancement handle between environment members.

### **3. Findings and discussions**

#### **3.1. Supply chain digital twin**

Conventional supply chains may now not be sufficient within the computerized age. Cutting edge markets advantage not as it

were from supply chain productivity, but too from its nimbleness and adaptability. Nowadays, the supply chain is advancing from a conventional show of straight, person, and no concurrent connections to a more associated and facilitated organize of commerce accomplices. The supply chain is expected to be restored, computerized and able to supply the desired administrations. Subsequently, it must advance through interconnected advanced gadgets and complex systems. This computerized supply chain interfaces distinctive partners (counting clients) more successfully and empowers them to reply speedier and adjust to a quickly changing advertise. Capgemini Counseling clarifies the five measurements of alter as takes after (Ageron, Bentahar, & Gunasekaran, 2020; Oubrahim & Sefiani, 2022).

- 1) Computerized supply chain methodology: The objective is to coordinated computerized developments within the in general supply chain methodology.
- 2) Supply Chain Administration and Operational Show: A particular computerized working demonstrate in which information now not depends on location. Large enterprises working all-inclusive will consider inside coordination committees in more detail.
- 3) Coordinates execution: Executing diverse supply chain capacities is exceptionally imperative. The most objective is to supply forms that give all the data required by representatives.
- 4) Coordinates supply chain execution estimation: This highlight makes it conceivable to track any arrange or exchange through a computerized working demonstrate. When utilizing barcodes or RFID labels, the utilize of labeling advances opens the way to getting real-time

data on physical relocation. A digital twin can be characterized as an energetic virtual representation of a protest or physical framework, utilizing real-time data to get it, learn, and reason. In spite of the fact that its definition changes from source to source, the most thought is to supply an advanced representation of a resource (unmistakable [presence] or intangible [framework]), which employments the Web of Things to get significant information in genuine time. And based on the created demonstrate, how it worked within the past and how it works presently, comes to the conclusion.

### **3.2. The importance of digital twin in supply chain planning**

The advanced twin was created with three fundamental components counting physical item (PP), virtual item (VP) and information trade. Advanced Twin has three vital highlights: synchronization between physical item and virtual item, comprehensive and energetic information collection, and high-quality virtual modeling. These three characteristics play a critical part in managing with arranging challenges. By synchronizing between the physical item and the virtual item, the computerized twin makes strides the speed of operation and responsiveness to decrease obtainment time. Arranging is based on data recovered from chronicled things and each unit within the supply chain. As a rule, there's a noteworthy time slack between target distinguishing proof, information collection, information trade, and execution. Synchronization between the physical item and the virtual item permits data to be shared between each unit and each design within the supply chain in genuine time, which essentially diminishes obtainment time. In expansion,

synchronization between the physical item and the virtual item upgrades the human-machine interaction between the supply chain and engineers. So, engineers can rapidly oversee the supply chain by changing virtual items. By powerfully and comprehensively collecting information, Computerized Twin altogether makes strides estimate exactness. As a rule, information collected from authentic cases are frequently not comprehensive sufficient to completely portray the situations they incorporate and the status of supply chain units or products. In differentiate, Advanced Twin powerfully collects information from different sources. Within the physical product, the advanced twin records real-time information of physical items, situations, comparable items, and administrators. Within the virtual item, the computerized twin extricates information from virtual models and reenactments. Chronicled case information is additionally put away. In expansion, distinctive advanced twins can have connected and trade information with each other, permitting the advanced twin to recover information from other frameworks. Subsequently, this tremendous information makes determining and arranging more exact over a longer period. With tall quality modeling, Computerized Twin improves arranging approval. A key approach to confirming arranging is simulation. Conventional computer program and instruments frequently incorporate insufficient natural components, rules, instruments, and behaviors. In differentiate, the computerized twin models all of this within the virtual item. Hence, the reenactment quality will be made strides, and the arranging confirmation will have less deviations.

### **3.3. Digital Twin-benefits in manufacturing**

Manufacturing is becoming smart at all levels from the physical device, through

factory management, to production networks, gaining abilities to learn, configure and execute with cognitive intelligence. Smart manufacturing is coined by several agencies, such as the Department of Energy (DoE) and the National Institute of Standards and Technology (NIST) in the United States. According to Davis et al., smart manufacturing is the dramatically intensified application of manufacturing intelligence' throughout the manufacturing and supply chain enterprise (Davis, Edgar, Porter, Bernaden, & Sarli, 2012; Iqbal et al., 2021). It comprises the real-time understanding, reasoning, planning and management of all aspects of manufacturing processes, facilitated by the pervasive use of advanced sensor-based data analytics, modeling, and simulation. NIST defines smart manufacturing systems as "fully-integrated, collaborative manufacturing systems that respond in real time to meet changing demands and conditions in the factory, in the supply network, and customer needs" In smart manufacturing, a physical 'thing' in a factory is connected to the Industrial Internet via standard cyber gateways and abstracted as a Digital Twin in the cyberspace. Each Digital Twin in the cyberspace is an abstraction of its counterpart in the physical world by reflecting its physical status. The cyberspace stores and processes the streamed data from connected physical objects. These data are used to model, simulate and predict the status of each physical thing under dynamic working conditions. The pervasive use of smart technologies, such as Big Data Processing and Artificial Intelligence enables the extraction of manufacturing intelligence at every single moment of manufacturing activities. The collective intelligence in locally connected factories and the cyberspace paves the way for some dramatic changes from the aspects of intra-business operation, inter-business collaboration and production model,

- **Smart Production:** Manufacturing systems augmented with cognitive intelligence (Amjad, Rafique, & Khan, 2021; Oubrahim et al., 2023) can take over more and more production jobs. Connected and self-organizing manufacturing systems will tackle new manufacturing tasks with high efficiency and flexibility. The relationship between humans and machines will also change; one direction is a factory will become fully-immersed human-machine collaboration space (Oubrahim, Sefiani, Quattrociochi, et al., 2022).
- **Smart Production Network:** Connected cyber-physical production systems will form a global production network that can respond in almost real-time to dynamic changes in local production systems and external supply chain (Bauer, Wollherr, & Buss, 2008). A production network of adaptive and self-optimizing production systems can enable autonomous configuration and planning of production activities for production jobs at changing scales to achieve sound economic, environmental and social impacts.
- **Mass Personalization:** Production model will move from a push type mass production model to pull-type mass personalization (Alfaro-Saiz, Bas, Giner-Bosch, Rodríguez-Rodríguez, & Verdecho, 2020; Li & Mathiyazhagan, 2018).

Smart factories that are fully responsive to changes and demands from the factory, supply chain, and customer side can achieve batchsize-of-1 production with high efficiency and flexibility. The ubiquitous manufacturing intelligence in distributed factories and production systems can sense,

configure and collaborate by themselves based on near real-time production status and demands, which therefore provides the required agility for producing highly personalized products.

#### 4. Conclusion

In conclusion, the paper emphasizes the importance of digitalization in the context of supply chain management and highlights the benefits of incorporating digital twins in manufacturing supply chains. The study identifies key prerequisites required for the successful development of digital twins, including data quality, system integration, and effective communication among stakeholders. By enabling companies to monitor and analyze their operations in real-time, digital twins can facilitate data-driven decision-making, improve efficiency, reduce costs, and enhance supply chain resilience. Moreover, the study shows that digital twins can create significant growth opportunities for companies through increased collaboration and the development of new service business models. The paper also emphasizes the importance of building a digital twin ecosystem to maximize the benefits of this technology. A digital twin ecosystem involves a network of companies and stakeholders that work together to develop and implement digital twins in their operations. This approach allows companies to share data and collaborate more effectively, leading to improved supply chain visibility, better decision-making, and increased efficiency. Furthermore, the study identifies several benefits of a digital twin ecosystem, including reduced risk, improved innovation, and the development of new business opportunities.

Overall, the paper provides valuable insights for academicians, practitioners, and businesses seeking to improve their supply chain operations through the use of digital twins. By highlighting the prerequisites for

successful digital twin development, the study helps companies to better understand the challenges and opportunities associated with this technology. Additionally, the paper emphasizes the benefits of a digital twin ecosystem and provides guidance on how to develop such an ecosystem. Ultimately, the

study demonstrates that digital twins are a powerful tool for improving supply chain efficiency, reducing costs, and enhancing competitiveness, and that companies that embrace this technology can gain a significant advantage in today's fickle and complex business environment.

## STRATEGIC DECISION-MAKING OF ORGANIZATION IN VOLATILE BUSINESS ENVIRONMENT

**Abstract:** *Organizational strategy provides the road map for every organization and ensures that decisions concerning the future are taken in a systematic and purposeful way. Strategic decisions are never simple to make. On one hand, biases in company decisions cannot be avoided since they are inherent to human nature which is mainly resistant to feedback. On the other hand, uncertain environment requires an organization to develop mechanisms to understand future scenarios and manage strategic risk. The paper deals with hazards and threats exerted on nowadays organizations that may generate their vulnerability. To mitigate vulnerability some strategic approaches are proposed as a response to challenges for World crisis that will perpetuate in coming years.*

**Keywords:** *strategy, management, uncertainty, quality, business excellence*

### 1. Introduction

Strategy has been dealt with by military people since Middle Ages thus first prescriptions concerning business strategy originate with military tests. However, in most contemporary business schools students are directed to study *business policy* by getting acquainted with scores of case studies elaborating the situations encountered in real business. By this heuristic approach students are trained specific circumstances of a company and consequently derive practicable solutions.

However, late 1960s emerged a systematic and analytic approach to strategy formulation and implementation. These analytical approaches to strategy strongly rely on the assumption that what occurred in the past is strongly connected with what might happen in the future.

In 1980s strategy frequently leans on the adoption of a set of ‘best practices’ what

may be regarded as a reflection of emerging business excellence. The idea was not to copy the solution from a company that made it excellent but to transpose some practices that might contribute to better results in own company. (Jelić, 2009)

Today’s corporate world is in the process of a global transformation. Acquisitions, mergers, downsizing and outsourcing are becoming common around the world. Strategic management takes a panoramic view of such chaining corporate landscape to show how big and small companies can become more efficient and effective in the years that come.

Strategic management consists of the set of managerial decisions and actions aimed to pave the way for the successful company performance in the long term. It encompasses environmental scanning, strategy formulation, strategy implementation, evaluation and control.

Strategic management provides the route map for the organization. It furnishes a framework to ensure that decisions concerning the future are taken in a systematic and intentional way. In addition, strategic management plays a major role as a hedge against uncertainty, i.e. a hedge against totally unexpected developments on the business horizon.

## 2. Strategy embracing uncertainty

A capital challenge of strategy facing uncertainty is to make choice instantly but the payoff takes place in future environment that is quite vague. A critical step in embracing uncertainty is to define exactly what variety is faced.

### 2.1. Bias at strategy setting

One of the problems may be found in unintentional fuzzy thinking. Behavioral economists have marked many brain characteristics that are strengths in our personal environment but can have negative effects in decision making process. They include overoptimism (tendency to hope the best and excessively believe in own forecasts or abilities), loss aversion (be emphasized on avoiding down-sides and escaping worth taking risks), anchoring (regarding own valuation of something to an arbitrary reference point), herding (feeling comfortable in following the crowd), the confirmation bias (overweighting statements that validate management opinion), and the champion bias (giving merit to an idea based on the person who proposes it).

Strategy is particularly susceptible to faulty logic since it relies on extrapolating ways to achieve success in the future from a complex set of factors recorded today. The two problems frequently encountered are attribution error and survivorship bias. Attribution error denotes the false attribution of success to observed factors, grounded on assumption that replicating the actions of

another company lead to similar results. Survivorship bias refers to an analysis based on surviving population, without reference to those who did not live to tell their view. This approach sees what caused success neglecting insight what might cause failure. (Lovallo&Sibony, 2006)

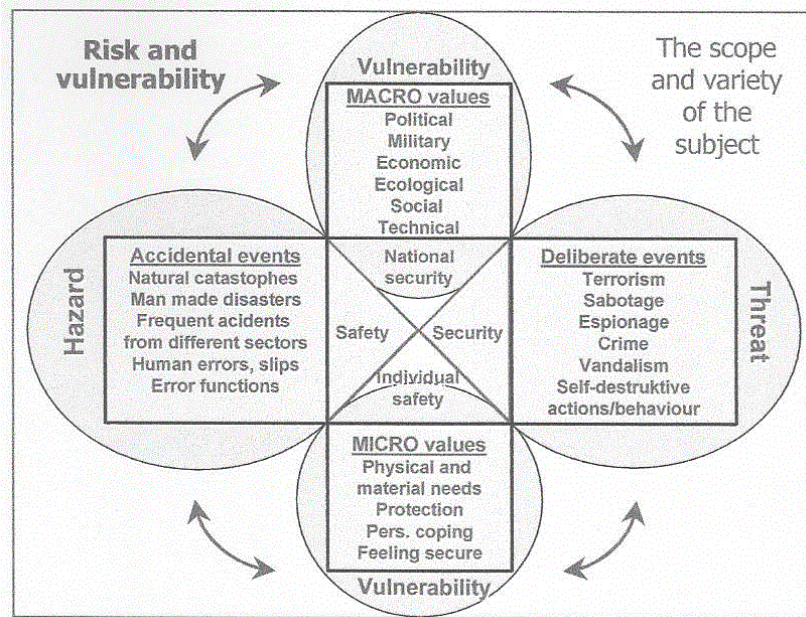

### 2.2. Risk at strategy setting

Eversince Aristotle who said: "It is probable that improbable will happen" dealing with risk and vulnerability issues have remained with many open questions. The new technological, nuclear, chemical and ecological, biologic, and genetic risks, along with political and social risks, such as terrorism, are difficult to separate and determine in time and space and to explain with the rules of causality to be able to compensate and to insure such risks, (Beck, 1992).

Figure 1 shows full variety of the subject. The vertical axis gives the links between international, national, local, and individual stressors at various levels. The key challenge is to coordinate information between the levels and vulnerability management systems. The horizontal axis shows that the field covers from natural events, accidentally man-made, technologically induced disasters to deliberate, malicious acts against others. Social vulnerability usually refers to problems linked to survival and recovery of vital societal functions, i.e. threats to infrastructures, energy supplies, and ICT (Hovden, 2004).

The dichotomy between natural scientific objectivism and cultural relativism can be paraphrased as follows (Lupton, 1999):

- Racionalist – One who sees risk as real world phenomena to be measured and estimated by statistics and controlled by scientific management.
- Realist – One who sees risk as objective hazards or threats that exist and can be

**Figure 1.** The vertical macro-micro perspective on risk management combined with types of hazards, threats, and events (Hovden, 1998)

estimated independently of social and cultural processes but may be distorted through social and cultural frameworks of interpretation.

**Constructionist** – One who sees nothing at risk in itself. What other sees as a risk the constructionist sees as a product of historically, socially, and politically contingent ways of seeing.

Middle positions lies between realist and constructivist theory. The proponents see risk as an objective hazard or threat that is inevitably mediated through social and cultural processes and can never be known if isolated from these processes.

### 2.3. Risk management strategies

To deal with the features of distinct risk types three combined risk management strategies are proposed (Klinke&Renn, 2001):

- Risk informed management strategies,
- Resilience based strategies,
- Discursive management strategies.

Risk informed management puts the stress on scientific assessment, reduction of exposure/ probabilities, risk management according to expected values on risks and benefits, and reliance on inspections and audits. Ostensibly, it may be used where there is sufficient knowledge of key parameters.

Resilience based management is characterized by an emphasis on transdisciplinary research and investigations, the containment of application (in time and space), constant monitoring, redundancy and diversity in safety design, firm liability and zero tolerance policy for risk control. This approach is used where high uncertainty or ignorance rate is encountered.

Discourse based management mainly focuses on reaching political consensus, the importance of procedure or transparency, the establishment of trust-generating institutions, the involvement of stakeholders, and public participation. Such approach is convenient for situations characterised by high ambiguity.

### **3. Levels of uncertainty**

Making right strategic decision under uncertainty cannot be obtained by applying a set of powerful analytical tools that is used in traditional approach to strategy. When the future is undoubtedly uncertain the traditional approach may lead to strategies that neither defend organizations against the threats nor may take advantage that higher levels of uncertainty may offer.

The uncertainty that remains after thorough analysis can be regarded as residual uncertainty. The residual uncertainty may have rates in a wide range but it is common to classify in one of four broad levels. (Courtney et al, 2005)

**Level I:** At this level, residual uncertainty is practically negligible, and managers are able to define their strategy based on one prediction. Although every business environment inherently carries elements of uncertainty, predictions are enough to guide strategy in one direction. To help generate this usefully precise prediction of the future, managers can use the standard strategy tool kit: market research, analyses of competitors' costs and capacity, value chain analysis. This level can be called the level of clear enough future.

**Level II:** Here, the future is viewed through several separate scenarios that can be played out. The analysis cannot determine which scenario will unfold, but it is significant if the probability of certain scenarios unfolding can be determined. In that case, usually the degree of elaboration of each alternative scenario is proportional to the probability of

its unfolding. For example, if a competitor opens a new capacity, it is likely to affect the price and placement of an organization's products.

Here, managers must develop a set of discrete scenarios based on their understanding of how the key residual uncertainties might play out. Each scenario may require a different valuation model. Getting information that helps establish the relative probabilities of the alternative outcomes should be a high priority. After establishing an appropriate valuation model for—and determining the probability of—each possible outcome, the risks and returns of alternative strategies can be evaluated with a classic decision analysis framework. Therefore, this level may be referred to as the alternative futures level.

**Level III:** At this level there is an area of possible development of the situation. That area is defined by a number of key variables, but the actual outcome can be found anywhere along that continuum. A lot of development strategies are at this level, for example: profit from new technologies, market share with a new product, companies entering new geographic markets, etc.

The analysis in level three is similar to that in level two: a set of scenarios describing alternative future outcomes must be identified, and analysis should focus on the trigger events indicating that the market is moving toward one or another scenario. Developing a meaningful set of scenarios, however, is less straightforward in level three. Scenarios that describe the extreme points in the range of possible outcomes are often relatively easy to develop but rarely provide much concrete guidance for current strategic decisions. Since there are no other natural discrete scenarios in level three, deciding which possible outcomes should be fully developed into alternative scenarios is a highly creative work. Establishing the range of scenarios should allow managers to decide how robust their strategies are as well

as to identify likely winners and losers. Complying above elaboration may be marked as a range of futures.

Level IV: At the last level of uncertainty, the number of dimensions of uncertainty creates such an environment that is impossible to predict. Here, it is impossible to predict the range of possible outcomes, let alone the scenarios within the field of possible events. Such situations are quite rare and they are related to politically unstable countries or to the appearance on the market of completely unknown technologies.

Situation analysis at level four is highly qualitative. Still, it is critical to avoid the urge to throw up your hands and act purely on instinct. Instead, managers need to catalog systematically what they know and what it is possible to know. Even if it is impossible to develop a meaningful set of probable, or even possible, outcomes, managers can gain a valuable strategic perspective. Usually, they can identify at least a subset of the variables determining how the market will evolve over time. They can also identify favorable and unfavorable indicators of these variables—indicators that will let them track the market's evolution over time and adapt their strategy as new information becomes available. Fortunately, level IV situations ordinarily does not last too much and turn to level III, and even level II, as soon as the environment begins to stabilize.

#### 4. Strategic responses in volatile business environment

After the outbreak of the global crises (the pandemic, the war in Ukraine), classic approaches to organizational strategy and modalities for their implementation can no longer be effective. Therefore, organizations shall incline to new strategies that will match the environment of highly elevated uncertainty. Some specific strategic governances are suggested by

*McKinsey & Company, 2023.*

- **Increasing speed, strengthening resilience** Volatility is a feature, not a bug in today's organizations. However, surveys show that half of companies declare to be unprepared to react to future shocks. Hence, those able to bounce forward may gain significant advantage over others. To be able to do so requires organizing for speed of response, giving power to the people, and developing a culture of continuous learning.

- **The new balance of in-person and remote work**

Since the pandemic, vast majority of organizations have embraced a range of hybrid work models that allow employees to work remotely from off-site locations (including home) for some or much of the time. The key issue for organizations was to provide structure and support around the activities best done in person or remotely. By remaining fully open to options for how, when, and where employees work, including with a reset of performance expectations, "true hybrid" organizations can distinguish themselves as destination workspaces.

- **Making way for applied AI**

Artificial intelligence doesn't just have the potential to supercharge a company's operations; it can also be used to build better organizations. Companies are already using artificial intelligence to create sustainable, long-term talent pipelines; drastically improve ways of working; and make faster, data driven structural changes to their organizations. As organizations embrace the opportunities offered by artificial intelligence, they need to focus on embedding its use in corporate culture, and being thoughtful about artificial intelligence-related risks and ethical concerns.

- **New rules of attraction, retention, and attrition**

People are revising their attitudes both toward work and at work. Employees who quit say it isn't just money, work-life

balance, professional development, or purpose that will bring them back to work in 2023: it's a combination of all those things. Organizations can respond by tailoring employee value propositions to individualized preferences in ways that can help close the gap between what today's workers want and what companies need.

• **Closing the capability gap**

Companies across sectors often announce technological or digital elements in their strategies without necessarily having the right capabilities in place to integrate them. To achieve a competitive advantage, organizations need to build institutional capabilities—that is, an integrated set of people, processes, and technology that creates value by enabling an organization to do something consistently better than its competitors do. That means filling gaps in their core activities, which are often the result of insufficient resources or inconsistent commitment.

• **Walking the talent tightrope**

Business leaders have long walked a talent tightrope—carefully balancing budgets while retaining key people. In today's uncertain economic climate, organizations need to focus more on finding ways to match top talent to the highest-value roles. The idea isn't new, but it's the right one in this era of hybrid work models, increased employee mobility, and skill shortages.

• **Leadership that is self-aware and inspiring**

Many organizations are focusing on diversity, equity, and inclusion (DEI), but in many cases, the initiatives aren't translating into meaningful progress. What's often missing is a clear link between DEI strategy and the business strategy. One path forward is for leaders to be more systematic early on, considering the objectives and desired level of impact from their programs. To realize DEI aspirations, leaders will need to identify opportunities for making progress within

their organizations, as well as for improving their external communities and society.

• **Mental health: Investing in a portfolio of interventions**

Roughly 90% of organizations around the world offer some form of well-being program. But global health and well-being scores remain poor, despite well-intended interventions. Research highlights the link between reports of poor mental health and wellbeing and organizational issues, including attrition, absenteeism, lower engagement, and decreased productivity. In current business environment, organizations need to refocus their efforts on addressing the root causes of mental-health and wellbeing challenges in a systematic way.

• **Efficiency reloaded**

In today's uncertain business climate, companies are refocusing attention on efficiency measures among key organizational priorities. Boosting efficiency is about more than managing immediate crises or getting the same work done with fewer resources. Deploying resources more effectively to where they matter the most promises substantial benefits, including improved organizational health, higher shareholder returns, and better and faster decisions.

## 5. Conclusion

Rising interest rates, high inflation, low unemployment, supply chain concerns, elevated commodity prices, low consumer sentiment, and febrile geopolitics are among factors leading to financial and economic volatility—and deepening uncertainty for company strategists. Company decision makers are to take actions that will provide it to remain successful.

The company is to use objective fact base to uncover opportunities for improvement. The more organization is committed to use facts to assess maximum benefits from changes,

the more confidence managers will have in pursuing ambitious goals.

Communicating a compelling reason why strategy changes are inevitable. Role modeling, developing talent and skills, and fostering understanding is the manner to assure people to stay on board.

Finally, to remain succesful in the volatile world the organization has to take care that the company's best talent is matched to company's crutial initiatives. Once business and talent priorities are fully in line the organization will have ability to deliver value generated in the company.

## BUSINESS PROCESS IMPROVEMENT. IMPROVEMENT OF INTERNAL CERTIFICATION PROCESSES

**Abstract:** *The purpose of this paper is to expose the processes which are important to run into the organizations.*

*Consumers around the world increasingly demand products and services that are simultaneously good for the economy, for the environment, and for society — the triple bottom line of sustainable growth.*

*Based on your existing systems, the Sustainable organization certificate demonstrates that you have implemented and documented processes with some elements of international standards (ISO 14001 and ISO 27001).*

*A Sustainable organization implements sustainability strategies that provide them with economic and cultural benefits attained through environmental and social responsibility and intensive care for employees. This rising demand is creating new pathways for businesses and governments to drive change for the global good. Developed countries are also home to sophisticated consumers whose choices drive business decisions worldwide and are increasingly aware of the triple bottom line of sustainable growth.*

**Keywords:** *Keywords: process, improvement, standards, certificates, method of work, guidelines, board*

### 1. Introduction

Processes play a crucial role in organizations at they provide structure, efficiency and consistency in carrying out tasks and achieving organizational objectives. Overall, processes are essential for organizations to operate efficiently, achieve their goals, maintain consistency, manage risks, and adapt to changing environments. By establishing effective processes organizations can enhance their performance, customer and employee satisfaction and long-term success. Arabi, M. 2007.

Among some essential roles that processes

fulfil in organizations are Efficiency and Productivity, Consistency and Quality, Clarity and Accountability, Risk management and Compliance, Scalability and Growth, Continuous Improvement, Customer Satisfaction, Decision Making and Agility and Knowledge Management. Dowey, J. (1929). Introduction.

Efficiency and productivity help streamline workflows and eliminate unnecessary steps or bottlenecks, leading to improved efficiency and productivity. Well-designed processes ensure that tasks are completed in a standardized and optimized manner, reducing wasted time, effort and resources.

Consistency and quality establish

---

Corresponding author: Marjetka Kastner  
Email: [marjeta@llacademia.com](mailto:marjeta@llacademia.com)

standardized procedures and guidelines for performing tasks, ensuring consistency and quality in the organization's outputs. By following established processes, employees can consistently deliver products or services that meet or exceed customer expectations.

Clarity and accountability provide clarity on roles, responsibilities and the sequence of activities required to accomplish specific tasks. This helps employees understand their responsibilities and be accountable for their work. Schoorman, F.D., Mayer, R.C., & Davis, J.H. (2007). Clear processes also facilitate effective coordination and collaboration among team members.

Risk management and compliance processes enable organizations to manage risks and ensure compliance with legal, regulatory and industry requirements. Processes can include checks, controls and approvals that help mitigate risks, ensure data security and adhere to relevant standards or regulations.

Well defined processes lay the foundation for scalability and growth within organizations. As the organization expands, processes can be replicated or modified to accommodate increased workloads, additional departments or new business units. Standardized processes also facilitate knowledge transfer and onboarding of new employees.

Continuous Improvement processes provide a framework for continuous improvement and learning within organizations. By monitoring and analysing process performance, organizations can identify areas for improvement, implement changes and optimize their operations over time. This continuous improvement mindset fosters innovation and enhances the organization's competitiveness.

Customer satisfaction processes directly impact customer satisfaction by ensuring consistent delivery of high-quality products or services. Well-designed processes consider customer needs, preferences and

feedback, allowing organizations to meet or exceed customer expectations. Customer-centric processes contribute to enhanced customer loyalty and positive brand reputation. Stephenson, K. (1998).

Decision making and agility processes provide valuable information and insights for decision making. By capturing data, metrics and feedback related to processes organizations can make informed decisions, identify areas requiring attention and allocate resources effectively. Flexible processes also enable organizations to adapt quickly to changing market conditions or internal dynamics.

Knowledge management serves as a mechanism for capturing and sharing knowledge within organizations. They facilitate the transfer of best practices, lessons learned and expertise among employees, ensuring that valuable institutional knowledge is preserved and leveraged. This promotes learning, innovation and knowledge continuity.

## **2. The organization and its basic composition**

Organizations often consist of various departments or functional units, each with its own specific role and responsibilities. The specific departments within an organization can vary depending on its size, industry, and structure.

It's important to note that the specific departments can vary significantly depending on the organization's industry, size and structure. Some organizations may have additional departments specific to their sector, such as a healthcare organization having a medical services department or a retail organization having a merchandising department, military offices have some defence departments etc.

We will introduce some common departments found in many organizations:

- 1) Human Resources (HR): The HR department handles matters related to recruitment, hiring, onboarding, training, performance management, employee relations, compensation and benefits, and overall workforce management.
- 2) Finance and Accounting: The finance department is responsible for managing the organization's financial resources, including financial planning, budgeting, financial reporting, accounts payable and receivable, payroll, and financial analysis.
- 3) Operations or Production: The operations department oversees the organization's core activities, such as manufacturing, production, service delivery, and process optimization. It ensures that products or services are delivered efficiently and in line with quality standards.
- 4) Marketing and Sales: The marketing and sales department is responsible for promoting the organization's products or services, conducting market research, developing marketing strategies, managing advertising and promotional campaigns, and handling sales activities to generate revenue. Bosh, T. 2013.
- 5) Information Technology (IT): The IT department manages the organization's technology infrastructure, including computer systems, networks, software applications, data management, cybersecurity, and IT support for employees.
- 6) Research and development (R&D): The R&D department focuses on innovation and new product development. It conducts research, experiments, and analysis to drive product improvements, explore new technologies, and stay ahead of market trends.
- 7) Customer Service: The customer service department handles inquiries, complaints, and support requests from customers. It plays a crucial role in maintaining positive customer relationships and ensuring customer satisfaction.
- 8) Administration or Operations Support: The administration department provides support services to the organization, including facilities management, office administration, procurement, logistics, and administrative support to various departments.
- 9) Legal and Compliance: The legal department ensures that the organization operates in compliance with relevant laws and regulations. Keil, F. C. (1989)., It handles legal matters, contract management, intellectual property protection and risk management.
- 10) Strategic Planning or Business Development: This department is responsible for long-term strategic planning, market analysis, identifying growth opportunities, mergers and acquisitions, partnerships, and overall business development.

### **3. What basic processes are carried out within the organization regardless of its composition**

In general, organizations consist of various processes that help them function and achieve their goals effectively. Here are some basic processes commonly found in organizations, but there's also some specific

processes and their implementation may vary depending on the nature, size, and industry of the organization.

**Communication:** Effective communication is essential for coordination, collaboration and sharing information within an organization. This process involves exchanging messages, ideas, and feedback through various channels such as meetings, emails, phone calls, and digital communication tools.

**Decision Making:** Decision-making processes involve analysing information, evaluating options, and choosing the best course of action to address organizational challenges or opportunities. Decision making can be hierarchical, where decisions are made by higher level authorities, or participatory, involving input from multiple stakeholders.

**Planning:** Planning involves setting goals, defining strategies, and developing action plans to achieve desired outcomes. It includes assessing the current situation, identifying priorities, allocating resources, and establishing timelines. Planning helps organizations anticipate future needs and align efforts towards achieving objectives.

**Organizational Structure:** This process involves designing the organizational structure, which determines how tasks, responsibilities and authority are distributed within the organization. It includes defining reporting lines, establishing departments or functional units and specifying roles and responsibilities.

**Human Resource Management:** Human resources processes involve activities related to managing and developing an organization's workforce. This includes recruitment, selection, training, performance evaluation, compensation and employee development. Human resources processes ensure that the organization has the right with the right skills to achieve its objectives.

**Operational Processes:** These processes are directly related to the organization's core

activities or production of goods and services. They may include manufacturing processes, service delivery processes, quality control, supply chain management and customer relationship management. Operational processes are specific to the nature of the organization's industry or sector.

**Monitoring and Evaluation:** Organizations need processes to monitor and evaluate their performance and progress towards their goals. This includes setting performance indicators, collecting data, analysing results and making necessary adjustments to improve performance. Monitoring and evaluation processes help organizations measure success, identify areas for improvement and make informed decisions.

**Continuous improvement:** Organizations should have processes in place to foster a culture of continuous improvement. This involves identifying opportunities for innovation, gathering feedback from stakeholders and implementing changes to enhance efficiency, quality and effectiveness.

**Figure 1.** Processes in organization

#### **4. The importance of knowledge in organization**

Knowledge plays a vital role in organizations and is considered a valuable asset. To effectively harness knowledge, organizations often implement knowledge

management practices, including knowledge sharing platforms, communities of practice, training programs, and knowledge documentation. By valuing and leveraging knowledge, organizations can enhance their performance, drive innovation and remain competitive in dynamic business environments. Among reasons why knowledge is important in organizations is: Decision Making where knowledge provides the foundation for decision making. It enables organizations to make better choices by drawing on insights, expertise and lessons learned from past experiences. Knowledge helps in evaluating alternatives, assessing risks, and considering various perspectives before making strategic or operational

decisions. On the other hand with knowledge we can solving problems. Organizations face numerous challenges and problems on a regular basis. Knowledge equips employees with the necessary information and expertise to identify, analyse and solve problems effectively. We can also prove that sharing knowledge within teams and departments enhances problem-solving capabilities and accelerates the resolution of issues. Of course we can approve that innovation and adaption is essential for fostering and driving organizational growth. By leveraging existing knowledge and encouraging the generation of new ideas, organizations can develop innovative products, services and processes. Rezayian, A. 2005.

**Figure 2.** Competitive advantage

Knowledge also enables organization to adapt to changing market conditions, technological advancements and customer preferences. Knowledge Is also a key driver of learning and development within organizations. By sharing knowledge and providing access to resources, organizations empower their employees to acquire new skills, expand their knowledge base and continuously improve their performance. This fosters a culture of learning, growth and professional development.

Knowledge is also a sticker for collaborations and teamwork. That means when employees have access to relevant knowledge and expertise they can collaborate more effectively share ideas and work together towards common goals. The enhances productivity, creativity and overall

team performance. Results shows that's organizations with knowledge has competitive advantage and effectively manage and leverage their knowledge and make strategic decisions that differentiate them from competitors. Is allows them to innovate, deliver superior products or services and create unique value capturing valuable propositions. Novak, J. (2009)

Most of leaders know that the organization is good as the people it keeps. Knowledge serves as the organizational memory, capturing valuable insights, lessons and experiences. By preserving and sharing knowledge, organizations avoid reinventing the wheel and benefit from past success and failures. This knowledge continuity ensures that valuable expertise and institutional knowledge are retained even when

individual employees leave the organization. Allen, T.d. (2003).

With all these knowledge components organization is on the highest level in customers eyes. Why? Because make customer satisfaction. Knowledge about customer's needs, preferences and feedback is crucial for delivering personalized and satisfactory experience. By leveraging customer knowledge, organizations can tailor their products, services and interactions to meet customer expectations. Robbinz, S. 2012. This leads them to higher customer satisfaction, loyalty and positive brand reputation. What else an organization need?

### **5. Creating a knowledge map in the organization as part of business process improvement**

In today's fast-paced business world, organizations are constantly seeking to improve their processes and increase their competitiveness. One area that has gained significant attention in recent years is knowledge management. Knowledge is recognized as a critical asset for organizations, and effective management of knowledge can lead to significant benefits such as increased innovation, reduced costs, and improved decision-making. One way to manage knowledge effectively is to create a knowledge map in the organization as part of business process improvement.

Creating a knowledge map in the organization as part of business process improvement is a crucial step towards achieving success in any organization. A knowledge map is a visual representation of the knowledge assets of an organization, including the people, processes, and technology that support the organization's goals. It helps to identify the knowledge gaps and opportunities for improvement in the organization's business processes.

A knowledge map is a visual representation of an organization's knowledge assets and how they are connected. It provides a comprehensive overview of the knowledge resources available within the organization, the locations where they are stored, and how they are used. A knowledge map can be used to identify gaps in knowledge, redundancies, and areas where knowledge is not being effectively utilized. It can also help identify potential areas for improvement and provide a framework for knowledge sharing and collaboration.

The process of creating a knowledge map involves several steps. The first step is to identify the knowledge assets within the organization. This includes both explicit knowledge, such as documents, reports, and databases, and tacit knowledge, such as skills, expertise, and experience. Keil, F. C. (1989). Once the knowledge assets have been identified, the next step is to map them. This involves creating a visual representation of the knowledge assets and how they are connected. The knowledge map can be created using a variety of tools, such as mind mapping software, concept mapping software, or even a simple spreadsheet.

After the knowledge map has been created, it can be used to identify areas for improvement. For example, the map may reveal that there are redundancies in certain areas or that certain knowledge assets are not being effectively utilized. This information can be used to develop strategies to address these issues and improve knowledge management within the organization. The knowledge map can also be used to identify areas where collaboration and knowledge sharing could be improved. By creating a framework for knowledge sharing, the organization can leverage its collective knowledge to drive innovation and improve decision-making.

Creating a knowledge map in the organization as part of business process improvement is a valuable tool for effective

knowledge management. It provides a visual representation of the organization's knowledge assets and how they are connected and can be used to identify areas for improvement and develop strategies for knowledge sharing and collaboration. The use of a knowledge map can lead to significant benefits for organizations, including increased innovation, reduced costs, and improved decision-making.

In addition to the benefits mentioned previously, creating a knowledge map can also help facilitate knowledge transfer during employee turnover or succession planning. It can also assist in identifying key knowledge experts within an organization and their specific areas of expertise.

The process of creating a knowledge map typically involves several steps. The first step is to identify the knowledge assets within the organization, including both explicit and tacit knowledge. This can be done through interviews, surveys, and other data collection methods.

The next step is to organize the knowledge assets into categories and subcategories based on their relevance and importance to the organization. This can be done using a variety of methods, such as mind maps or hierarchical diagrams.

Once the knowledge assets are organized, the next step is to identify the relationships between them. This can be done by mapping the connections between different knowledge assets, such as identifying which pieces of knowledge are required to understand others.

Joseph D. Novak's book, *Learning, Creating, and Using Knowledge: Concept Maps as Facilitative Tools in Schools and Corporations*, provides a comprehensive guide to using concept maps as a tool for knowledge mapping. Novak argues that concept maps are an effective way to organize and represent knowledge, as they allow individuals to visualize complex

relationships between different concepts.

In the book, Novak provides detailed instructions on how to create concept maps, including tips on selecting appropriate concepts, creating meaningful links between them, and using visual cues to enhance understanding. He also discusses the use of concept maps in educational settings, noting that they can be used to improve student learning and assessment by providing a way to measure understanding of complex ideas.

Furthermore, Novak discusses the value of using concept maps in corporate settings. He notes that concept maps can be used to identify gaps in knowledge and develop strategies for improving knowledge management within organizations. By mapping out an organization's knowledge assets, it becomes easier to identify areas where knowledge is lacking and to prioritize knowledge management efforts.

Overall, Novak's book highlights the value of using concept maps as a tool for knowledge mapping in both educational and organizational settings. By providing a visual representation of knowledge, concept maps can help individuals and organizations learn more effectively, promote communication and collaboration, and prioritize knowledge management efforts.

Finally, the knowledge map should be reviewed and updated regularly to ensure it remains relevant and up-to-date.

Overall, creating a knowledge map is a valuable tool for improving knowledge management within an organization. It provides a comprehensive overview of an organization's knowledge assets and can assist in identifying gaps, redundancies, and areas where knowledge is not being effectively utilized. By leveraging the power of a knowledge map, organizations can improve decision-making, reduce costs, and drive innovation. *Behavior*, 62, 134-154.

In general, developing a knowledge map is a useful tool for enhancing knowledge

management inside a company. It offers a thorough picture of a company's knowledge assets and can help find gaps, duplications, and places where knowledge isn't being used properly. Organizations may enhance decision-making, lower costs, and stimulate creativity by utilizing the potential of a knowledge map.

## 6. Knowledge transfer - the importance of mentoring in organizations

As mentoring has been in existence over a number of centuries; various theories on the origin of mentoring have been put forward by different people. Some scholars familiar with the original work of mentoring believe that the true origin of the modern use of the term more likely comes from the work of 18th Century French writer Fenelon, also an educator. African scholars have however noted that mentors were commonplace in Africa, long before the ancient Greek Civilization (Merlevede & Bridoux 2004:6).

In any group, there are people with more experience and knowledge and those with less. Connecting these two groups is vital to the smooth running of any organisation, so the formal and informal knowledge can flow easily between people, connecting them between themselves and the organisation's cause, best practised through mentorship. The main goal of mentoring is a quality development of an individual on personal, business and career levels. Mentorship is greatly valuable when it comes to hands-on, quality transfer of knowledge, but it can also help the people within the organisation feel a sense of belonging and guidance. L.M.,&Poteet, M.L. (2009).

Within organisations can be present formal and informal modes of mentoring both with different advantages. The organisation establishes a formal mentoring structure, including specific guidelines and goals, with

designated mentors and mentees. In informal mentoring, however, the mentor and mentees usually meet spontaneously and decide how to work together. Members of the organisation can also become more productive and at ease with their work since they receive hands-on advice from real-life experience and lessons from mentors. Crocitto, M., Sullivan, S.E.,&Carraher, S.M. (2005). Mentorship can save money for the education of employees and time searching for good resources because mentees learn directly from a mentor and their experience. Cascio, W.F.,&Aguinis, H. (2008).

### 6.1. Mentorship for entrepreneurs

If we move on to smaller organisations and individual entrepreneurs, we can see a great demand for mentorship in that area as well. Every person has at one point dealt with loneliness and isolation in some area of their life. Entrepreneurs and self-employed individuals are at even greater risk than most, as the covid 19 pandemic has shown us. Isolation and the absence of a feeling of belonging can kill the creative and business drive we all depend on to run our business. From this immediate need, an idea of mentorship was born within a small non-profit organisation in Slovenia. One entrepreneur started connecting with other like-minded individuals who felt the same need: to connect, educate each other and learn and, most importantly to support each other where needed. Entrepreneurs are incredibly curious individuals, and often we also need to share all the knowledge we gather.

Information and knowledge have also never been more accessible as they are now. With the rise of online classes and programs, one can get so easily lost in what is genuinely quality content. In response to this, organisations have started seeking out individual and curated mentorship and guidance. Mentors can recognise

individual's or group's unique needs and advantages. Every human being is different. Our learning styles, tempos and confidence vastly vary from individual to individual, but when we can adapt to the needs of a specific person or a group, their potential starts coming alive. Allen, T. D., Finkelstein,

For example, the before mentioned entrepreneurial organisation Podjetni became a specific tool that brings together those who offer knowledge and those who seek it. The organisation went through a process of research and experience to create

- a series of events that focus on connecting mentors and mentees,
- an online platform where mentors in almost every area can be easily highlighted and reached,
- a system that offers individuals free consultations from all the mentors,
- educational academies and programs based on the mentorship values for a qualitative transfer of knowledge. Buckley, G. (2001).

Mentorship also saves time. Instead of listening to broad educational classes on foreign study cases and examples, mentorship directly addresses the immediate needs of an entrepreneur. Mentors will help a person on their own work, so they can walk out of the door with already-applied results. An organisation like Zavod Podjetni, which connects multiple mentors, means a person can painlessly switch from area to area depending on their need. If they first need help with branding, they can later move on to direct sales and content writing with a different but in familiar and certified system.

## 6.2. Qualities of mentors

No matter who and what they are teaching, there are specific attributes a mentor has to embody. A mentor has to be a stable and continuous force in someone's life on who the mentee can always depend and look up.

They give guidance and assignments and challenge the mentee, but they do not do the work for them, so they can properly learn. When the mentor learns mentees life and business situation, their goals, challenges and ambitions, they can guide them if they ever stray from the mentees desires path. Wanberg, C.R., Welsh, E.T., & Hezlett, S.A. (2003). An individual also often just needs someone who will listen and offer a shoulder, and that is where the mentor guides as a therapist figure who helps them holistically. In the end, mentor also acts as a guardian since a mentees are often in vunrable position of learning and growing. Merlevede & Bridoux 2004:6). The mentor has to be emphatic to them, but they should never get involved personally into an individual's story.

Mentorship is becoming more recognised and sought after every year, in areas of personal and business growth. Mullen, E.J., & Noe, R.A. (1999). Small and large organisations are recognising the benefits of quality mentorship, which helps them save time and money, but also create deeper and more personal connections to the knowledge in the organisation.

## 7. Tools for measuring the performance of processes in the organization

There are several tools and techniques available for measuring the performance of processes in an organization. The selection of specific tool depends on the nature of the process in an organization. The selection of a specific tool depends on the nature of the

Process and the organization's objectives.

It's important to select the most appropriate tools based on the specific needs and objectives on the organization. Additionally, organizations may choose to combine multiple tools and techniques to gain a comprehensive understanding of process

performance and drive continuous improvement.

We will focus just on some commonly used tools for measuring process performance.

Very good tool for measuring is also Life Learning Academia certificate system. The process guide board team through the activities and questionnaires. When organization complete all the requested activities and fill all the questionnaires can show the results. Actually this is the

Current stage of the organization. This bigger picture shows all the gaps which need to be filled. Process last among 4- 6 month.

Another very important tool is Key Performance Indicators (KPI). KPIs are quantifiable metrics used to assess the performance and progress of specific processes or activities. KPIs should be aligned with organizational goals and can vary depending on the process being measured. Examples of KPIs include customer satisfaction scores, on-time delivery rate, process cycle time, defect rate, revenue growth and employee productivity.

Balanced scorecard is strategic performance measurement framework that considers multiple perspectives, including financial, customer, internal process and learning and growth perspectives. It provides a holistic view of the organization's performance and helps align process measurement with strategic objectives.

Process Mapping involves visually representing a process flow to identify bottlenecks, inefficiencies and areas for improvement. By mapping out the process steps and analysing the inputs, outputs and interactions, organizations can measure performance and identify opportunities for optimization.

Employee Feedback and performance evaluations can provide insights into the effectiveness of processes. Regular feedback, performance metrics, and performance appraisals help measure

individual and team contributions to process performance. Dewey. *Advances in Knowledge Organization*. 4, 109-117.

Customer Feedback and Survey is valuable tool for measuring process performance from the customer's perspective. Surveys, focus groups and customer satisfaction metrics can provide insights into the effectiveness of processes in meeting customer needs and expectations.

Data Analytics and Business Intelligence tools: Advanced analytics tools and technologies, such as data dashboards, predictive modelling and data mining, enable organizations to measure process performance by analysing large volumes of data. These tools provide real-time insights, identify trends and support data-driven decision making.

Six-Sigma is a data-driven methodology aimed at reducing process variations and defects. It utilizes statistical tools and techniques to measure process performance, such as process capability analysis, control charts and defect rates. Six Sigma focuses on improving process quality and achieving near-perfect performance levels.

Lean Manufacturing/Lean Six Sigma: Lean methodologies, often combined with Six Sigma, focus on eliminating waste and maximizing value. Tools such as value stream mapping 5S and Kaizen events are used to to measure and improve process performance by streamlining workflows, reducing lead times and enhancing overall efficiency.

Benchmarking involves comparing an organization's performance against industry best practices or competitors. By measuring key process metrics and comparing them to external benchmarks, organizations can identify performance gaps and set improvement targets.

Process Audits involve systematic evaluations of process adherence, compliance and effectiveness. Audits can be

conducted internally or by third-party experts to measure process performance, identify non compliance issues and recommend improvements.

## 8. Conclusion

Processes are vital components of organizations, serving multiple essential roles. They provide structure, efficiency and consistency in carrying out tasks, leading to improved productivity and quality. Key processes within organizations include those related to communication, decision making, planning, human resources management, operational activities, monitoring, evaluation and continuous improvement.

By establish all described processes organizations can enhance their efficiency, productivity, customer satisfaction and overall performance. Processes also

contribute to risk management, compliance, scalability and knowledge management within organizations. For organizations is also important to regularly review and improve their processes to adapt to changing environments, technological advancements and customer expectations. With well-designed and effectively implemented processes organizations are better equipped to navigate challenges, seize opportunities and achieve their strategic objectives.

Good processes provide a way to communicate and apply consistent standards and practices within the business, it helps the employees what needs to happen and creates a path for growth. Good processes save time and increase overall efficiency and take are built around the customer and users' needs. The most important thing is to manage employees on properly manners.

## USE OF INTEGRATED MCDM APPROACH FOR THE SELECTION OF LEAN TOOLS TO IMPROVE THE ORGANIZATIONAL- BUSINESS PERFORMANCE

**Abstract:** *There are numerous strategies and concepts that management can use in order to improve the organizational business performance of companies in modern business conditions. Research shows that one of the most prevalent principles in the past few years is the use of Lean tools, which enable managers to continuously improve their business. Since in most cases the problem of choosing Lean tools is solved through experience, the paper proposes the application of an integrated multi-criteria approach for decision-making. The evaluation of the relative importance of the criteria was performed using the AHP method, while the selection of the most suitable Lean tool was carried out using the ELECTRE method, the PROMETHEE method and the Compromise Programming method, using specially developed software for that purpose. The aim of this paper is to point out the importance and quality of the application of the proposed model in real and modern conditions of business and organization.*

**Keywords:** *Lean tools, Multi-criteria decision making, AHP method, ELECTRE method, PROMETHEE method, Compromise Programming method*

### 1. Introduction

Modern business conditions require companies to continuously improve their organizational and business performance in a high-quality manner. Due to increasing market competition and increasingly complex customer requirements, companies are required to produce higher quality products, shorter delivery times and lower costs. Many companies face more and more challenges in finding ways to improve performance, which needs to be updated almost on an annual basis. These circumstances only make it difficult to choose the most appropriate approaches,

techniques and tools, as they should be applicable and add value to the enterprise.

The paper will present a proposal for a multi-criteria decision-making (MCDM) model of appropriate Lean tools for quality improvement of organizational and technical performance of companies in the metalworking industry. In practice, no single Lean tool can solve all problems and respond to all challenges an organization faces. All Lean tools have their advantages, but also certain limitations, which is why it is necessary to choose a group of the most suitable tools. The managerial initiative to improve quality and improve the company's performance refers to approaches to the use

and implementation of the Lean concept and various tools in production systems (Hobbs, 2004; Hobbs, 2011).

Information technology is essential for the practical application of business decision-making methods. In this way, different methodologies of multi-criteria decision-making can be implemented in practice. Modern methodologies of multi-criteria decision-making are becoming more and more complex and sophisticated. The task of information technology is to support these methods, but on the other hand to enable users to use them easily. This paper presents a program for using multi-criteria ranking methods using Promethea, Compromise ranking and Electra. The specificity of this program is the possibility of visual presentation and analysis of preferences according to certain criteria using the calculation of the Universal Preference Function. This function allows the creation of an unlimited number of preference functions. The program enables their simple and comparative visual analysis as well as a comparative presentation of the results of other methods of multi-criteria analysis.

## **2. Selection of the most effective Lean tools based on defined criteria**

By reviewing the literature, many authors propose the Lean concept, that is, the use of Lean tools as one of the best and most effective ways to improve the organizational and business performance of a company. The ability to choose the appropriate tools and techniques of lean manufacturing, taking into account several critical criteria for decision-making, provides a significant improvement in the quality of business

(Yahya et al., 2016; Belekoukias, Garza-Reyes & Kumar, 2014). In practice, it has been shown that the use of Lean tools achieves a significant reduction in waste (Leksic, Stefanic & Veza, 2020). According to (Gonzalez et al., 2016) they can serve as a powerful tool for increasing the efficiency of the company. These tools measure the efficiency and quality of work performance (Pakdil & Leonard, 2014). A study conducted by (Reda & Dvivedi, 2022) suggests an innovative approach in selecting appropriate lean tools to maximize the company's core resources, while the case study (Kumar et al., 2021) showed a direct improvement in productivity and improved customer service. The findings presented in research of (Alaskari, Ahmad & Pinedo-Cuenca, 2016) revealed that the proposed methodology was effective in identifying appropriate lean tools for companies, according to key performance indicators in the SME manufacturing sector. Improvements in operational and environmental performance are demonstrated with a change in Lean tool application status (Liu, Niu & Li, 2022).

### **2.1. Selection of Lean Tools**

A significant role in the application of Lean tools in manufacturing companies is played by customers, who can directly influence the added value of the product. They don't attach much importance to the organizational and production activities of the manufacturer, but are exclusively interested in the quality, correctness and functionality of the product. Table 1. shows some of the most important Lean tools that the management of manufacturing companies use in order to qualitatively improve organizational and business performances.

**Table 1.** The most important Lean tools for quality improvement of organizational and business performance

	Lean Tools	Definition
a <sub>1</sub>	5S	5S is a five-step methodology for creating a more organized and productive workspace: sort, straighten, shine, standardize and maintain.
a <sub>2</sub>	Value Stream Mapping (VSM)	VSM is a flow chart that documents each step involved in the material and information flows required to bring a product from order to delivery. It is used in continuous improvement to identify and eliminate waste, reduce process cycle times, and implement process improvements.
a <sub>3</sub>	Plan-Do-Check-Act analysis (PDCA)	PDCA - Managers set targets (plans), Teams implement improvements (Do), then they measure (Check) the change to evaluate performance against the target. If the target is accomplished, it standardizes (Acts) the new method by updating the standardized work.
a <sub>4</sub>	Poka-Yoke (error avoidance)	Poka-Yoke is a technique that aims to minimize or completely eliminate the possibility of errors and defects resulting from errors, as well as to reduce the possibility of transferring defective products to the next production stage, or to the end user.
a <sub>5</sub>	Single-Minute-Exchange of Dies (SMED)	SMED is used in manufacturing to reduce equipment changeover time, it can also help reduce costs and increase flexibility within the process.
a <sub>6</sub>	Takt Time	Takt Time represents the quotient of the planned production time and the time required by the customer. It is a method for determining the production rhythm, thereby aligning production with customer requirements.
a <sub>7</sub>	Total Productive Maintenance (TPM)	TPM is the process of using machines, equipment, employees and supporting processes to maintain and improve the integrity of production and the quality of systems.

## 2.2. Criteria to be considered when selecting Lean Tools

The most important step in the application of multi-criteria decision-making methodology is the selection of alternatives and criteria that the decision-maker should consider, in the example of manufacturing companies, these are managers. The criteria for choosing the optimal alternative are of a diverse nature, and managers are required to perform an analysis and selection of criteria with regard to the qualitative improvement of organizational business performance.

Below are presented the criteria on the basis of which the considered alternatives were evaluated: **C1: Costs** (Costs of scrap and processing; of production per unit; of product; of product development; of transport; Inventory costs etc.); **C2: Quality** (Standardization of procedures and processes; Return rate of customers; Flow

time or production time; On-time delivery percentage etc.); **C3: Productivity** (Productivity of labor; Equipment utilization; Capacity utilization; Number of bottleneck stages etc.); **C4: Innovations** (Time to launch new products; Time spent on engineering changes; No. of proposals per employee per year; No. of new products introduced etc.) **C5: Flexibility** (General flexibility; Product expiration date; Percentage of production equipment that is digitized or automated etc.); **C6: Competitive advantages** (Annual gross profit; Total sales; Market share; Product price etc.) **C7: Morality** (Number of awards and rewards for employees; Employee turnover rate; Communication between employees and management etc.)

### 3. Application of an integrated MCDM approach when selecting lean tools

The paper presents the MCDM model based on the integration of the AHP and PROMETHEE methods, the ELECTRA method and the Compromise Programming Method. It is shown on the example of the evaluation of alternatives when choosing Lean tools for quality improvement of the organizational and business performance of a manufacturing company, which are the most significant in practice. The selection was made between seven alternative tools evaluated in a system of seven criteria. Since the management of the company makes these decisions in modern and dynamic business conditions, in order to perform an accurate evaluation of the considered alternatives, it is necessary to apply the

Integrated MCDM approach. The AHP method is used to evaluate the criteria used to evaluate the alternatives, where the weight coefficients obtained below for each criterion will be further used in the process of evaluating the alternatives using the modified PROMETHEE, ELECTRA and Compromise Programming methods (Radojicic et al., 2013). The evaluation process was carried out using specially developed software, where a comparative view of the results will be presented by applying these three methods.

#### 3.1. Evaluation of the weight of the criteria using the AHP method

The hierarchical structure of the problem developed by the AHP methodology is shown in Figure 1.

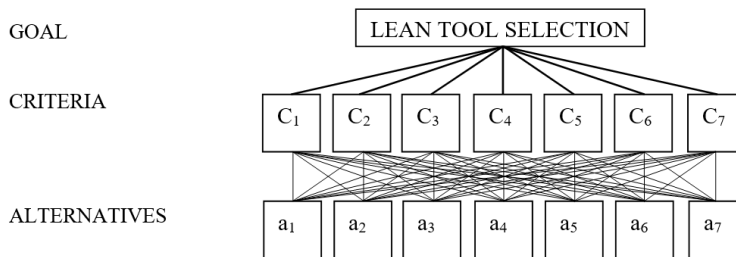

Figure 1. The hierarchy of the decision-making problem

The influence of the criteria on the choice of Lean tools depends on the subjective assessment of the decision maker, in this example the manager, in the conditions of uncertainty in which the decision is made. This would mean that any of the criteria can become crucial in the choice, depending on the situation, and that, also, depending on the criteria used, each of the alternatives can dominate over the others. In order to perform a correct and rational evaluation of the alternatives, it is first necessary to evaluate the relative importance of each individual

criterion. The criteria assessment matrix is given in Table 2.

The assessment matrix is further translated into a criteria priority scale by normalizing the weight vector of each individual criterion, the relative importance of the criteria is obtained (Table 3) according to the decision maker's priorities in the considered situation.

**Table 2.** Revised matrix of pairwise comparison of criterion weights

	C <sub>1</sub>	C <sub>2</sub>	C <sub>3</sub>	C <sub>4</sub>	C <sub>5</sub>	C <sub>6</sub>	C <sub>7</sub>
C <sub>1</sub>	1.0	0.5	3.0	5.0	6.0	4.0	7.0
C <sub>2</sub>	2.0	1.0	4.0	6.0	7.0	5.0	9.0
C <sub>3</sub>	0.33	0.25	1.0	4.0	5.0	2.0	6.0
C <sub>4</sub>	0.2	0.17	0.25	1.0	2.0	0.33	4.0
C <sub>5</sub>	0.17	0.14	0.2	0.5	1.0	0.2	3.0
C <sub>6</sub>	0.25	0.2	0.5	3.0	5.0	1.0	0.17
C <sub>7</sub>	0.14	0.11	0.17	0.25	0.33	6.0	1.0

**Table 3.** Criteria weights specified using AHP methods

Criteria	Criteria weight
C1: Costs	0.244742
C2: Quality	0.355284
C3: Productivity	0.142258
C4: Innovations	0.060537
C5: Flexibility	0.04235
C6: Competitive advantages	0.085935
C7: Morality	0.068895

The obtained results indicate that the "Quality" criterion with a weight coefficient of 0.355284 dominates over the other criteria, and the "Flexibility" criterion with a weight coefficient of 0.04235 was the least dominant. This solved the problem of conflicting criteria and imprecise information for their definition and assessment, and the obtained results served in the further process of evaluating alternatives.

### 3.2. Process of evaluation of alternatives using modified PROMETHEE method

For the considered MDCM problem the evaluation matrix (Table 4) was constructed, which compliantly with the defined hierarchical structure of the problem (Figure 1) encompasses the 7 alternatives assessed in the system of 7 criteria. The evaluation matrix was constructed on the basis of the impressions that managers, involved in the decision-making process, gained during the testing of Lean tools, as well as on the basis of the existing organizational and business performance of the company.

To solve the problem of decision-making and ranking of alternatives, in situations where qualitative criteria are present, the application of the modified PROMERHEE method is suggested. For each criterion, the same type of universal preference function was selected that most appropriately reflects the specifics of the given criteria, after which parameters were determined, as well as requirements for extremism (Figure 2). For the relative weights of the criteria, the results obtained in the previous procedure of evaluating the criteria using the AHP method were used (Table 3).

**Table 4.** The evaluation matrix

	Criteria			Alternatives						
	Relative Weights	Request	Type of preference function	a <sub>1</sub>	a <sub>2</sub>	a <sub>3</sub>	a <sub>4</sub>	a <sub>5</sub>	a <sub>6</sub>	a <sub>7</sub>
C <sub>1</sub>	0.244742	MIN	Universal	2.35	8.14	9	7	1.48	5.73	4.06
C <sub>2</sub>	0.355284	MAX	Universal	7.21	8.49	6.15	8	3.3	4.07	9.2
C <sub>3</sub>	0.142258	MAX	Universal	9	8	4	3	6	7	5
C <sub>4</sub>	0.060537	MAX	Universal	2.6	7.2	9.5	1.1	4.1	3	5.8
C <sub>5</sub>	0.04235	MAX	Universal	1.83	2.97	4.71	2.32	5	3.45	0.64
C <sub>6</sub>	0.085935	MAX	Universal	5.09	8.83	9.14	7.22	6.84	8.19	5.73
C <sub>7</sub>	0.068895	MAX	Universal	10	1.5	8	4	2	7.5	5.5

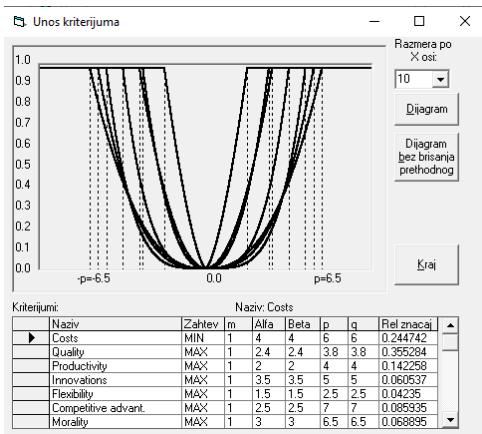

Figure 2. The Universal preference functions for criteria

The further ranking procedure of the considered alternatives according to the modified PROMETHEE methodology was carried out with the use of specially developed software.

The obtained results (Figure 3) indicate that the alternative “5S” singled out as an alternative that has the greatest impact on the improvement of the organizational business performance of the company.

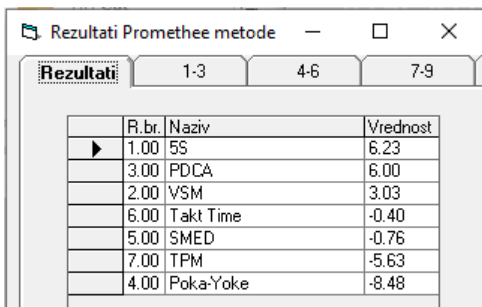

Figure 3. Evaluation of the alternatives using the modified PROMETHEE method

### 3.3. Process of evaluation of alternatives using ELECTRE method

Furthermore, the ranking of alternatives was performed using the ELECTRA method,

based on the parameters from the evaluation matrix (Table 4).

The following ranking of alternatives was obtained (Figure 4), where we can see that it differs from the ranking obtained by the analysis using the modified PROMETHEE method, and that the best ranked alternative is “TPM”.

Figure 4. Evaluation of the alternatives using the ELECTRA method

### 3.4. Process of evaluation of alternatives using Compromise Programming method

Also, the ranking of alternatives was performed using Compromise Programming method, based on the parameters from the evaluation matrix (Table 4).

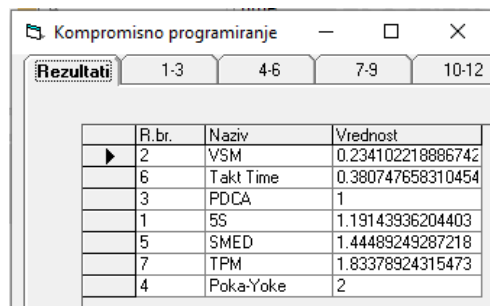

Figure 5. Evaluation of the alternatives using the Compromise Programming method

Based on the ranked alternatives (Figure 5), we can also see that the final ranking of the alternatives is different from the results of

the previous two methods, and that the best ranked alternative is “VMS”.

#### 4. Conclusion

The results of the comparative analysis of the evaluation of alternatives using three different MCDM methods indicate different rankings of the alternatives. So it can be concluded that none of the proposed Lean tools is dominant compared to the others. The proposed model reduces subjectivity when making decisions and generates much more rational solutions, based on reliable assessment of the weight of criteria, structuring of problems and overcoming problems. On the other hand, the modified PROMETHEE method improves the quality of decision-making by assigning appropriate

universal preference functions to each of the criteria and enables a rational ranking of the considered Lean tools. While the application of specially developed software provides decision makers with ease of use, speed and eliminates the possibility of error when solving problems. Therefore, further research is possible on the selection of appropriate lean tools, taking into account several critical decision criteria in modern business conditions.

## THE IMPACT OF HORIZONTAL AND VERTICAL SYSTEM INTEGRATION ON QUALITY 4.0

**Abstract:** *The era of Industry 4.0 insists on the necessity of understanding the connection between the strategy of horizontal and vertical system integration with Quality 4.0. A key segment for the effective implementation of Quality 4.0 is the creation of an organizational system that combines vertical and horizontal integration. In the paper, an overview of the literature related to Quality 4.0 and the mentioned integration in Industry 4.0 was given, and the importance of their understanding in Industry 4.0 was pointed out. Also, the focus of the work is on pointing out advantages, challenges and presenting solutions to overcome these challenges. The motive of writing the paper lies in the fact that there is no paper in which these concepts are combined. The aim of the paper is to consolidate in one place a review of the available literature from these areas in order to achieve progress towards Industry 4.0.*

**Keywords:** *Horizontal and vertical integration, Industry 4.0, Quality 4.0, Quality Management system*

### 1. Introduction

The development of Industry 4.0 technologies had an identical and parallel impact on quality management practices that changed quality management methods and practices (Sader, S., Husti, I., & Daroczi, M., 2022). New technologies of Industry 4.0 enable the minimization of complications and errors, the improvement of process effectiveness through a significant increase in the quality of the final product (Javaid, M., Haleem, A., Singh, R. P., & Suman, R., 2021), productivity, standardization of processes (Zaidin, N. H. M., Diah, M. N. M., Yee, P. H., & Sorooshian, S., 2018), transformation of culture, leadership, cooperation and compliance (Jacob, 2017).

Globalization, turbulent conditions on the market, rapid development of information and communication technologies and digital

networks are causing a change in the classic business models of organizations. This creates a completely new world of functioning systems for horizontal and vertical integration (Chukalov, 2017) and conditions the application of new business trends called Industry 4.0, i.e. the introduction of a new quality management practice known as Quality 4.0. In order to adapt, managers and then employees must change their awareness and culture to a great extent, but also improve their skills in using Industry 4.0 technologies (Chiarini & Kumar, 2022).

By integrating the quality management system and the basic technologies of Industry 4.0, organizations are given the opportunity to effectively and adequately respond to the numerous challenges they face, such as the struggle for survival in the market and maintaining a competitive

---

Corresponding author: Aleksandra Jovičić<sup>1</sup>  
Email: [jovicic.aleksandra32@gmail.com](mailto:jovicic.aleksandra32@gmail.com)

advantage. For this reason, there is an increased need to understand the connection of horizontal and vertical integration with quality 4.0 in order to better protect the intellectual property of the organization (Subramaniam, 2021).

Due to the extremely small number of available literature sources that connect Quality 4.0 and horizontal and vertical integration, the author's idea was to unite in one place the advantages and challenges related to horizontal and vertical integration in the new era of business. This is where the motive for writing this work comes from.

The paper pointed out the importance of the connection between horizontal and vertical integration and Quality 4.0, as a central and key element of Industry 4.0. This integration with quality 4.0 achieves a positive influence with each other. Also, the paper pointed out the importance of the relationship between horizontal and vertical integration and Quality 4.0.

The contribution of the work is reflected in a tabular representation of the advantages and challenges of horizontal and vertical integration and Quality 4.0, with a proposal for possible solutions to those challenges.

The work is organized as follows: Section 2 refers to the basics of the concept of Quality 4.0 and horizontal and vertical integration of the organization's system. Section 3 of the work describes the research methodology - method, sources and methods of collected samples of published works and tabular presentation of research results and discussion. The last part of the paper contains the conclusion.

## **2. Impact of horizontal and vertical integration on quality 4.0**

In Industry 4.0, there is a need to increase the understanding of horizontal and vertical

integration in which to better protect the intellectual property of the industry (Finance,2015; Subramaniam, 2021), due to the emergence of a new value network, as well as new business models (Sony, M., Antony, J., & Douglas, J. A., 2020). Accordingly, the interaction of implemented systems integrated into digital networks creates a completely new world. The interaction between machine and machine, machine and Internet, machine and person in the value chain, in real time forms the basis of the modern manufacturing cyber system (Chukalov, 2017) and has a long-term impact on the company's business strategy (Sewak, 2022).

The use of certain Industry 4.0 technologies could have a positive effect on quality control and management, and therefore on improving the horizontal and vertical integration of the system. Also, the quality management system in the concept of Industry 4.0 could, on the one hand, contribute to better horizontal and vertical integration, while on the other hand, it could benefit from the use of technologies such as Data Mining, analytics, cloud systems and feedback in decision-making. based on the evidence. Node.js®, Node Package Manager (NPM), MongoDB, Angular, Laravel and MySQL can be used to develop and maintain quality system documentation in the Industry 4.0 concept (Stefanović, M., Đorđević, A., Puškarić, H. & Petronijević, M., 2019).

### **2.1. Quality 4.0**

Given the lack of a generally accepted definition of quality 4.0, some authors define the concept of quality 4.0 in different ways (Aldag, M. & Eker, B., 2018). The term "Quality 4.0" was first used by the analytical company LNS Research in 2017, which defines Quality 4.0 as a set of the latest quality management practices and tools that are applicable for use in the context of Industry 4.0 (Akhmatova, M. S., Deniskina,

A., Akhmatova, D. M., & Prykina, L., 2022) state that quality 4.0 combines new technologies with traditional quality methods in order to reach new optimums in operational excellence, performance and innovation. (Sader et al., 2022) defines quality 4.0 as an expanded approach to quality management, where the latest technologies are integrated with traditional quality practices to expand the scope of quality management and improve quality management. (Salimova, T., Vatolkina, N., Makolov, V., & Anikina, N., 2020) defines quality 4.0 as a new understanding of the relationship and responsibility of stakeholders, the transformation of the basic principles on which decision-making in companies is based. In addition to the confirmation of the importance of combining

innovative methods of quality management and digital technologies, it has been shown that this process implies the transformation of managerial thinking itself.

The digital transformation of traditional quality cannot be carried out without the implementation of quality 4.0 tools (Richnák, 2022) and therefore, Industry 4.0 technologies are a key factor for understanding how to manage and improve quality processes in the Industry 4.0 era (Carvalho, A. V., Enrique, D. V., Chouchene, A., & Charrua-Santos, F., 2021). Quality management practices are proposed to identify technological progress as a key factor for the successful implementation of quality standards in the era of quality 4.0 (Sader et al., 2022), (Table 1).

**Table 1.** Quality management practices and technology relationship in Industry 4.0 (Carvalho et al., 2021)

I4.0 Tools and Technologies	Quality management practices							
	Management of obligations	Customer involvement	Supplier participation	Employee involvement	Benchmarking techniques	Process management	Information and analysis	Formal strategic planning
Data Science and Statistics	X					X	X	X
Enabling Technologies (IoT, IIoT, Integrated Systems, VR, AR, Cloud Computing (CC))	X	X	X	X	X	X	X	X
Big Data	X	X	X			X	X	
Blockchain	X			X		X		X
Artificial intelligence - AI	X			X			X	
Machine learning - ML	X						X	X
Neural Networks and Deep Learning	X					X	X	

Table 1 shows the relationship between quality management practices and seven tools and technologies that can be used to improve quality, in order to facilitate the decision of the type of tool that is most adequate for certain quality management practices.

## 2.2. Horizontal integration

In order to efficiently produce products and services, inter-organizational horizontal integration should be formed, which is made up of related corporations. In this way, an efficient system is formed, in which there is a smooth flow of materials, information and finances between these organizations. In the sub-module of horizontal integration,

activities such as planning, control and quality improvement are oriented towards all organizations that collaborate within the value creation process to produce products and services (Sony et al., 2020).

In Industry 4.0, horizontal integration implies the integration of information technologies and production systems with the established exchange of data and information between companies in geographically distant locations throughout the value chain (Chukalov, 2017). This is achieved through the provision of networking through cyber-physical systems, from inbound logistics through warehousing, manufacturing, marketing and sales to outbound logistics (Finance, 2015).

Horizontal integration takes place on several levels (Schuldenfrei, 2019):

- At the production level - connected machines and production units constantly communicate their status and respond autonomously to production demands.
- In multiple production plants - through production execution systems (MES) data about production plants (eg inventory levels, unexpected delays) is shared throughout the company.
- Throughout the supply chain - Suppliers and service providers must be firmly integrated horizontally into the company's production control and logistics systems.

Examples of successful horizontal integration include Microsoft - Activision Blizzard, Anheuser-Busch InBev and SABMiller, Walt Disney Company and 21st Century Fox (Moltz, 2022; Traver, 2022).

### 2.3. Vertical integration

Vertical integration occurs when organizations decide to expand by

purchasing a company that occupies a critical place in their supply chain process (Moltz, 2022) in order to gain control over the entire production process by integrating different levels of the organization ("Horizontal and Vertical System Integration in Industry 4.0", 2023), minimizing or eliminating the need for external subjects (Amadeo, 2022).

This type of integration in Industry 4.0 uses cyber-physical production systems (CPPS) to enable rapid response to changes in demand or inventory levels and to errors (Finance, 2015). Vertical integration of hierarchical subsystems such as different departments within the factory implies that physical (sensors, control) and informational subsystems (ERP and SAP) are integrated at different levels within the production system in order to create a flexible production system. Quality 4.0 as a sub-module for vertical integration deals with all activities of quality improvement, control and planning, within the organization (Sony et al., 2020).

Examples of vertical integration can be cited (Cook, n.d.; Traver, 2022): Walmart - JoiRun, NVIDIA - Bright Computing, Google and Motorola - Alphabet's Google (GOOG), Ikea and forests in Romania, Netflix (NFLX).

## 3. The importance of quality 4.0 on horizontal and vertical integration

### 3.1. Research methodology

This paper is based on a systematic review of the available literature. Available literature sources from Google scholar, researchgate, springer, science direct were used. Manual search was performed in Google Scholar and Google Chrome, and automated search in Science Direct and Springer.

The search at the mentioned locations was performed by entering keywords into the search engine. Various combinations of keywords were used to search for articles, such as: Quality 4.0, quality 4.0 and industry 4.0, horizontal and vertical integration and quality 4.0, horizontal and vertical integration in industry 4.0.

Papers were reviewed and selected, which, based on the analyzed titles, keywords and abstracts, were relevant to the main research topic of this paper. 23 relevant literary sources were used in writing this paper. The articles that were used for this paper were mostly published after 2018. with certain exceptions.

### 3.2. Research results and discussion

In this part of the work in table 2, based on the available literature in this area (Amadeo,

2022; Chukalov, 2017; Cook, n.d.; Finance, 2015; “Horizontal and Vertical System Integration in Industry 4.0”,2022; Moltz, 2022; Pipiyay, G. T., Chernenkaya, L. V., & Mager, V. E., 2021; Schuldenfrei, 2019; Sewak, 2022; Traver, 2022) the challenges of horizontal and vertical integration are shown and suggestions are given for overcoming these challenges and the advantages of those solutions are shown in Quality 4.0. Table 3 shows the advantages of horizontal and vertical integration to quality 4.0. In this way, topics from this area are united in one place. Based on a detailed analysis of the presented tables, it is easier to make a decision within the organization whether to choose one type of integration or both in accordance with the specifics of each company and in accordance with the needs and goals of the organization.

**Table 2.** Presentation of the challenges of horizontal and vertical integration with their solutions and the demonstrated advantages of those solutions to quality 4.0

Challenges	Integration	The solution
Data management - Analysis of accumulated data and knowledge in all sectors of the organization	Vertical and horizontal	Changing the organizational culture, the way of working and the awareness of employees for the use of intelligent systems, the use of digital technologies, such as IoT devices and blockchain, for the collection and sharing of quality data, production units equipped with a wide range of sensors, the establishment of a meta-network
Improvement of IT systems and infrastructure	Vertical and horizontal	Moving to cloud-based IT
Adopting a strong platform for managing and coordinating multiple computer systems and applications	Vertical and horizontal	Investing in the acquisition and updating of a suitable strong platform
Data security and availability	Horizontal	Moving to cloud-based IT
Standardization	Vertical	Implement a quality management system (QMS) that integrates quality management processes in various departments and functions
	Horizontal	Establishing clear quality standards and requirements for suppliers and regular monitoring and evaluation of supplier performance.
Cultural barriers	Vertical	Developing cross-functional teams that include representatives from different departments and functions.
	Horizontal	Developing partnerships and collaboration with other organizations in the supply chain to improve communication and collaboration
Costs	Vertical and horizontal	Using analytics and predictive modeling, continuous improvement that includes regular review and evaluation of quality management practices.

**Table 3.** Advantages of horizontal and vertical integration on quality 4.0

Quality 4.0 and horizontal integration	Quality 4.0 and vertical integration
Consistent quality throughout the supply chain	Consistent quality across functions within the organization
Improved cooperation and communication with other organizations	Improved communication and collaboration within the organization
Increased efficiency and productivity (Automation, flexibility and operational efficiency in production processes)	Increased efficiency (Quick resolution of change orders, fluctuations in quality or machine failure, reducing waste)
Resource efficiency in terms of efficient use of materials, energy and human resources	
Reducing downtime	
Dynamic management of quality, time, risk in real time	
Improved visibility and traceability	
Improved quality control (more efficient and accurate)	
More efficient decision-making (accuracy, systematicity and agility)	

In order to lead the organization towards industry 4.0, in addition to understanding its tools, it is necessary to understand and successfully implement quality 4.0 and establish connections with horizontal and vertical integration, which serve as key business strategies of the organization towards the key goal.

Industry 4.0, and therefore the quality of 4.0, is characterized by new tools and technologies, and the problems they carry due to insufficient knowledge in the sense of using the right technology in the right place, in this case, is also an advantage, with their proper use, which can be solved by understanding horizontal and vertical integration strategies, by adopting new knowledge and changing culture and awareness in order to achieve sustainability on the market and achieve progress towards industry 4.0.

Among the major problems of the successful introduction of these concepts are problems with large amounts of information, data and their processing (Pipipay et al., 2021), which are successfully solved with the help of modern tools and industry 4.0 practices and quality 4.0. Also, costs can be high due to the acquisition of Industry 4.0 and Quality 4.0 technologies, additional investments in employee training, but in the long run it is profitable. In order to avoid costs related to the inadequate implementation of horizontal

and vertical integration and the introduction of inadequate new technologies for a certain organization, it is necessary to change the culture, understand the strategies of horizontal and vertical integration and provide the necessary knowledge about new technologies.

What characterizes Industry 4.0, and therefore also Quality 4.0, are decision-making agility, successful integration with new technologies, and analysis of large amounts of data. With the proper implementation of horizontal and vertical integration in the new era of industry, quality has been improved and its control and management has been facilitated in all sectors. Also, efficiency in the use of resources and productivity are increased, costs are reduced, communication within and outside the organization is improved, which automatically leads to a reduction in costs and waste.

**4. Conclusion**

For the successful implementation of Quality 4.0, proper selection of business strategies that will lead the organization towards Industry 4.0 and maintaining competitive advantage is necessary.

Correct understanding of the use of horizontal and vertical integration in the era of Industry 4.0 and their impact on aspects of Quality 4.0 is of key importance for the

future successful operation of the organization. If implemented correctly, each of the integrations will bring benefits to the organization. The motivation for writing the paper lies in the fact that there is not a large number of scientific research papers dealing with this topic.

In order to better understand the advantages of each integration, the paper first gives an overview of the literature in the field of Quality 4.0 and horizontal and vertical system integration. After defining the key concepts, the advantages of each of the

integrations are tabulated so that organizations can decide which type of integration is best for them based on the goals and strategy of the organization. An overview of the advantages and challenges of horizontal and vertical integration of systems related to Quality 4.0 is given in the form of a tabular presentation, with proposed solutions to these challenges.

Further research will be focused on barriers related to the introduction of quality 4.0 in organizations and ways to overcome these challenges.

## THE APPLICATION OF AHP IN ASSESSING QUALITATIVE ASPECTS OF WORK: A CASE STUDY OF A MUNICIPAL COMPANY

**Abstract:** *The article presents the use of the ahp in the evaluation of work in a selected municipal enterprise operating in one of the agglomerations in Poland. Based on the case study, the use of AHP was presented in terms of overall evaluation of jobs of municipal company, which enabled to determine the hierarchy of organizational positions due to the difficulty and arduousness of work. . The research proceedings were supplemented by document analysis, structured interviews, team work methods, and classification technique. The article shows that such an approach ensured, on the one hand, the inclusion of qualitative aspects of tasks performed at individual positions in the assessment of work difficulties, and ensures team coordination of assessments and opinions, promoted in quality management, on the basis of which decisions regarding remuneration are made.*

**Keywords:** *job evaluation, analytical hierarchy process, jobs ranking, municipal company*

### 1. Introduction

Rewarding system for employees is perceived as the predominant total quality management dimension that affects employees' performance (Bahjat, Khaled 2022). Rewards system that encourages employees play the major facilitating role in stimulating consumer satisfaction and continuous improvement programs (Koval et al., 2018). Essential in this regard is a proper remuneration system (Basera, Mwenje 2021, Bullinger, Wolfram 2002), which is fair, equitable, and consistent for everyone. Fair wage is wage that is reasonable for type of work done. In the reference to organization, fair wage address the relative value of the job (not the job holders) compared to other jobs in order to achieve the internal justice. the generally accepted thesis is that only job

evaluation makes it possible to develop a fair remuneration system (Armstrong et al., 2005, Arthur, 2015, Dogan et al., 2014).

Job evaluation is a systematic process of assessing the difficulty and nuisance of work to identify the relative value or size of jobs in an organization in order to establish internal relativity and provide the basis for designing a fair grade and pay structure, grading structure and relativity management (Armstrong et al., 2003). The main aim of job evaluation is to provide an acceptable rationale for determining the pay of existing hierarchies of jobs and for slotting in new ones (Arthur, 2015).

Job evaluation depends on the results of the job analysis that produce both the job description and specification, which allows to counterbalance the difference in job values by differences in wage levels (Balshy,

Ismael 2023). In that respect job evaluation encompass the elements of qualitative and quantitative assessment of work. Job evaluation, as the method of reducing wage inequities (Kutlu et.al, 2013, p. 659) is most common method for determining pay in over 75% of US organisations (Dogan et.al, 2014). The job evaluation can be analytical or non-analytical. Analytical one is about evaluating each of profession in organization basing upon a group of criteria, which enables to assess the difficulty and nuisance of work. Non-analytical are: job ranking, paired comparison, job classification (Armstrong et al., 2003, p. 19).

The key issue is to prevent job evaluation's results from subjectivity, therefore it is crucial to implement analytical decision making in job evaluation, in particular analytic hierarchy process (AHP). In order to prevent inequity problem and analytically support managers in job evaluations, in determining job evaluation criteria weights there is used AHP (Dogan et al., 2014), or more sophisticated fuzzy AHP (Senol, Dagdeviren 2019, Feng et al., 2023).

Though, the use of AHP in identification the ranking of company's jobs is relatively rare. Thus, paper presents the implementation of analytic hierarchy process in elaboration of ranking of jobs of the one of the municipal company in Poland. In that respect, the AHP was used in establishing the hierarchy of organizational positions due to the difficulty and arduousness of jobs. The research procedure was supplemented with document analysis, structured interviews, teamwork methods and a classification technique.

## **2. Data and Method**

The research study was conducted in one of the municipal enterprise in Poland, i.e. autonomous municipally owned corporation (MOCs) owned by municipalities outside the local bureaucracy, which have tariffs and commercial revenues, and produce and

deliver local public services (Voorn, et.al., 2017, p. 820). The decision-making problem was the assessment of 75 blue-collar jobs (see Fig 1). The study used data obtained in November-December 2022. Data were gathered from following internal sources of information: the scopes of responsibilities of jobs as well as the results of interviews with executive staff and employees in particular posts. Interviews – based on check lists forms (work sheets) – were conducted with the heads of organizational units and employees in order to gather information on the determinants of the difficulty and arduousness of jobs. Interviews were preceded by a review of the formal scopes of relevant duties. Interview sheets and the collected organizational documentation (organizational charts, formal job descriptions) were a basis for the next stage conducted by a team of 28 experts (composed of company executives), who had deep knowledge of the tasks and responsibilities at work positions. Team of experts were supposed – during one-day meeting – to assess the difficulty and arduousness of company's jobs using AHP.

Analytic hierarchy process is one of the multiple criteria decision method (MCDM) widely described and used by many academics, starting T. L. Saaty (2000) who created this method. Contemporary researchers such Prusak and Stefanów (2014) and Kułakowski (2020) attempted to explain this tool using a step-by-step approach. The first stage of the AHP is to build a decision-making, hierarchical model, which usually consists of the main goal, "parent" criteria, their "children" subcriteria (or factors) and decision variants. In the next stage, the hierarchy is evaluated using fundamental, 9-point pairwise comparison (PC) scale, where two alternatives are compared pairwise against each other with respect to the element one level above in the hierarchical structure. Assuming the criteria A, B and C, and their respective sub-criteria

A1, A2, A3; B1, B2, B3; C1, C2, C3, the example comparisons will be as follows: *With respect to B, which element is more preferred (important): A1 or A2? How much is this preference of one element over another?* There are 9 options: from “1” – A1 and A2 are equally preferred, to “9” – A1 has an extreme preference over A2, or A2 over A1. Based on these judgments, the square PC matrices (PCMs) are constructed, and subsequently, local priorities (weights) are calculated using one of a dozen prioritization methods. The results are presented as ranking vectors, indicating which element is the most preferred (important), and which is the least preferred.

Alongside priorities, the consistency ratio (CR) should be derived for each PCM, and if it exceeds 0,10 (10%), an inconsistent matrix should be modified by reconsidering the most inconsistent judgment. Then, global priorities can be calculated as multiplication of (local) priority for the parent criterion and (local) priority of its children sub-criterion. They indicate how meaningful is a given factor for the whole hierarchy. Finally, if the preference analysis is made by the group of experts, all their individual priorities must be aggregated into common ranking vectors using geometric mean. All these AHP stages have been applied in this research.

### 3. Results and discussion

The decision-making problem was the assessment of physical workstations from the point of view of their difficulties and strenuous work. 75 jobs were assessed, which were categorized into two groups, i.e. Core business jobs and Support activities jobs. This division results from the nature of the work performed. The overall model is shown in the diagram (Figure 1).

The analysis was carried out using the R language, the AHP package. The presented results refer to average values (from all respondents). According to Saaty's recommendations (Saaty 2000), those matrices were included in the analysis for which the CR coefficient is less than 0.20 (20%).

The global ranking is the main part of the research, allowing to determine the degree of nuisance and difficulty of work of each of the analyzed positions. To increase the transparency of the analysis, the positions were divided into four groups:

1. Group I (see: Tab. 1) - positions with the highest global priorities, i.e. those involving the greatest, very high difficulty and arduousness of work. It has been assumed that global priorities for these positions are from 2% and above. During the research, two positions with priorities above 6% were identified
2. Group II (see: Tab. 2) - positions with a medium-high value of global priorities, i.e. associated with medium-high difficulty and arduousness of work. It was assumed that global priorities for these positions range from 1.0-1.9%.
3. Group III (see: Tab. 3) - positions with an average value of global priorities, i.e. associated with an average difficulty and arduousness of work. It has been assumed that global priorities for these positions range from 0.5-0.9%.
4. Group IV (see: Tab. 4) - positions with a low value of global priorities, i.e. involving relatively low difficulty and arduousness of work. It has been assumed that global priorities for these positions are below 0.5%.

The team-worked ranking of jobs due to the difficulty and arduousness work difficulties with the use of AHP was accepted by the team members. Thus, it reflects the recognized, and indirectly acceptable, hierarchy of work difficulties in ranking jobs. It is worth mentioning that the developed ranking of positions, before it is adopted as input for the remuneration system, must be verified by applying analytical job evaluation with numerous criteria analyzing the content of work on evaluated jobs.

#### 4. Conclusion

The paper investigates procedure for using AHP in developing a ranking of positions of municipal company. Having employed the firm-level data, there was found that AHP is methodologically adequate technique of comparing of difficulty and arduousness of company's jobs. AHP is especially applicable where there are complex decision-making processes, which in relation to job evaluation refers to a relatively large number of positions to be compared with each other. Basing upon multiple experts knowledge a clear hierarchy of difficulties and arduousness of work in individual positions was agreed. So this approach, which includes teamwork and all aspects of employee, is in line with the key practices of

TQM (Pratima et al., 2022, Srinivasaiah et al., 2023).

Further research in the studied municipal enterprise ought to identify whether the ranking of positions developed using AHP is consistent with the results of analytical job evaluation. The direction of further research defined in this way, on the one hand, results from the need to verify the ranking of positions using AHP. On the other hand, it directly results from the methodology of job evaluation, which assumes that prior to starting the analytical job evaluation, a ranking of the evaluated positions should be developed (Armstrong et. al., 2005). Such a ranking, developed by company employees (working as a team) who have in-depth knowledge of the work content of the evaluated jobs, is to reflect the generally accepted hierarchy of difficulty and arduousness work difficulties in the company. It should be remembered that the remuneration system developed on the basis of the results of work evaluation is a social contract at the enterprise level. In other words, the hierarchy of work difficulties of individual positions, and ultimately differences in pay levels must be acceptable to employees and fair.

## AN APPROACH FOR BUSINESS- MANUFACTURING SYSTEMS MODELING IN ORDER TO APPLY OPTIMIZATION PROCESSES

**Abstract:** *The optimal production program is based on the assumption that there are quantitative measures of comparison with other admissible solutions, and is often a compromise between the desired goals and constraints which act as a condition for achieving extreme solutions. The importance of optimization of the production is significant because it is the basis for all other plans. The purpose of this paper is to propose an approach for modeling the business-production system in order to determine the optimal production program. The paper deals with the applied simulation and optimization processes by which the mentioned system can lead to optimum-required state. A mathematical model was defined using the linear programming method and the results were presented using the Mathematica software package.*

**Keywords:** *Optimization, Production program, Software package Mathematica*

### 1. Introduction

Business-manufacturing systems (BMS) belong to a group of organizational, complex, dynamic, stochastic, and open systems, and as such, tend towards their own degeneration if various approaches to the application of optimization processes are not continuously implemented.

The question of the production program is of strategic importance for the business, survival, and development of BMS. It is natural for managers to aim for an expected-desired state that is also optimal. However, desires are always hindered by constraints that must always be taken into account when applying optimization methods and techniques. In market business conditions, the production program represents the result of the optimal use of production potentials while respecting real market constraints. If the BMS has "excess" capacity, it means that

it is not optimally utilizing its capacity through specific contracts, and it is necessary to determine the reason for this through appropriate expert teams. If there is a "shortage" of capacity, it means that the demand is greater than the production capacity. Then, it is necessary to identify "bottlenecks" in production and remove them through more efficient organization or investment, thus creating conditions for fulfilling contractual obligations.

The researchers aim to define a mathematical model that enables finding optimal solutions at different levels of management and from different aspects. According to Joppen et al. (2019), the biggest challenge is optimizing the overarching production planning and the lack of an overall optimum. The following methods are most commonly applied for production planning: LP (linear programming), NLP (nonlinear programming), and MILP (mixed integer

linear programming) (Kallrath et al., 2005). Numerous studies deal with this issue, and a small part of it is presented in this paper.

Joppen et al. (2019) present a practical framework for optimizing production management processes, which represents a holistic approach to optimizing production planning and control processes. Their framework describes how conflicting objectives can be systematically analyzed and how a reasonable operational status can be derived. The authors address issues related to medium and short-term production planning, including defining goal analysis, initial state analysis, and optimization.

Trachenko et al. (2021) developed an economic-mathematical model for the rational formation of a business process management system in the engineering services sector, taking into account the time factor. The results of using the optimization model for the management of business processes such as design, electro-maintenance, production of electrical equipment, commissioning and adjustment, and consulting were presented.

Hervert-Escobar & López-Pérez (2020) propose an optimization model that maximizes the fulfilment of requirements, taking into account typical constraints from production planning formulations, as well as production constraints in real-life scenarios such as limited product changeovers and minimum machine run lengths. The authors utilized a mixed-integer programming model.

Various models can be found in the literature, such as: a model (two linear programming models) for maximizing Net Present Value (Petridis et al., 2020); a model for minimizing the aggregate production costs (Golari et al., 2017; Naeem et al., 2013); a model for optimizing the input technical effectiveness and efficiency of production process (Donini & Barbiroli, 1997); a mixed integer linear programming

model for optimizing the placement of composite parts in an autoclave (Dios et al., 2017); a mixed integer linear programming model for integrating production, inventory, distribution, and routing decisions in a single framework (Miranda et al, 2018); a model for finding the optimum production rate in factories that use seasonally produced raw materials (Kioulafas & Kapralos, 1980); a fuzzy multi-objective linear programming model that formulates the problem of mold production and outsourcing decisions (Wang et al., 2013); a cost model for evaluating the cost and benefit analysis of implementing Industry 4.0 elements in the production plant (Alami & ElMaraghy, 2021).

This paper aims to propose a different approach for modeling BMS in order to determine the optimal production program from the perspective of maximum utilization of available workforce capacity, within a one-year time interval, and to strive to describe the production system, as a hierarchical system with multiple levels, by a mathematical model. A mathematical model will be defined for the selected business-production system, using the method of linear programming, and the results will be presented by applying the Mathematica software package.

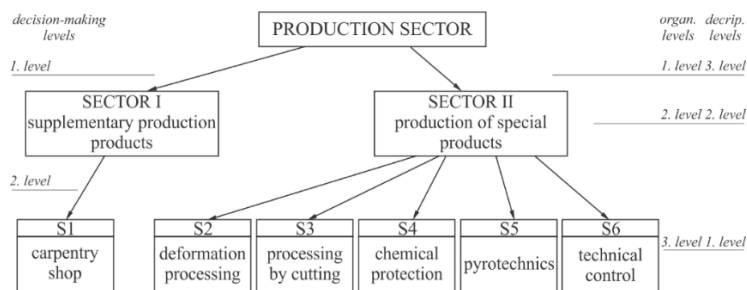

## 2. Defining the Mathematical Model

We can explore the optimal production program at the level of the BMS as a whole or at the level of its subsystems. If we model the BMS as a system that cannot be further broken down, then we determine the optimal production program at one level. The corresponding parameters in the mathematical model are usually grouped at the product level and constraints at the level of the system as a whole. However, optimizing the production program of a BMS by considering it as a complex system, consisting of multiple subsystems (possible

horizontal and vertical decomposition), is a much more complex task. The question arises whether the optimum at the system level is also the optimum at the subsystem level, i.e., whether there is a unity of goals between subsystems and the system as a whole.

When studying and modeling hierarchical systems, it is necessary to define organizational levels, description levels, and decision-making levels. Constraints in the model are closely related to organizational levels, management criteria for decision-

making levels, and corresponding parameters in the mathematical model can be grouped at the level of products, parts, or technological variants of production. The long-term aspect of the production program is usually based on assumptions and predictions, where qualitative elements prevail. Short-term production program planning is based on facts, with quantifiable elements prevailing. Depending on the adopted concept of programming orientation, from prediction to short-term planning, various methods and techniques can be used.

**Figure 1.** Hierarchical representation of the selected BMS Defining the coefficients in the mathematical model

As the goal of this paper is to determine the optimal production program from the perspective of maximizing the use of available workforce capacity and to describe the production system using a mathematical model, the most suitable method is linear programming (LP). The advantage of using this method is that there is a well-developed procedure (method) for solving such problems. However, it should also be noted that the application of LP is based on the assumption that relevant variables are deterministic, which does not correspond to reality, as they are stochastic variables. In this context, it is necessary to thoroughly investigate all parameters that are included in the model and perform a sensitivity analysis so that the obtained solution has practical value. The application of the LP method involves defining a mathematical model consisting of an objective function or

management criterion and a set of constraints. Figure 1 shows a system model in the form of a graph, with a hierarchical arrangement of subsystems and connections between levels. Vertical decomposition is performed with three organizational levels, three levels of description, and two levels of decision-making. The mathematical model for production optimization in the matrix form is presented by equations (1) – (4). Relation (1) represents the objective function that needs to be maximized, taking into account the optimal solution from the perspective of maximum utilization of available production human resources. Constraints (2) define the available production human resource capacities (B), while constraints (3) define the minimum (D) and maximum (G) market demands. To apply software tools, it is necessary to

represent the mathematical model in an expanded form.

$$\max F(x) = C \cdot X \quad (1)$$

$$A \cdot X \leq B \quad (2)$$

$$D \leq X \leq G \quad (3)$$

$$X \geq 0 \quad (4)$$

The mathematical model enables finding optimal solutions at the system level as a whole (first decision-making level, third description level), with constraints on the available human resources defined at the third organizational level (level of work units). The production plan includes 41 products ( $X_i$ ). To define the coefficients (elements of matrices C, A, B, D, and G) in the mathematical model, it is necessary to determine: total manufacturing time at the product level ( $c_i$ ); manufacturing times for current products by work units ( $a_{ij}$ ); available potential of production human resources ( $b_i$ ), in accordance with Relation (5); market absorption capacity ( $d_k$  and  $g_k$ ). If market constraints are not included in the mathematical model, it is assumed that everything produced can be sold.

**Table 1.** Overview of the necessary data for the calculation of the coefficients  $b_i$

$S_i$	$z_i$	$p_{ni}$	$\eta_{ri}$	$b_i$
S1	85	1,10	0,75	135166
S2	182	1,22	0,75	320987
S3	235	1,19	0,74	398879
S4	38	1,19	0,73	63628
S5	222	1,18	0,72	363549
S6	71	1,25	0,71	121457
$D_r = 257$ (work./yr), $C_s = 7,5$ (h/shift)				

Table 1 shows an overview of available workforce capacities per work unit ( $S_i$ ) i.e. the coefficients  $b_i$  in the mathematical model are defined.

$$b_i = z_i \cdot \eta_{ri} \cdot D_r \cdot C_s \cdot p_{ni} \quad (5)$$

Where:  $D_r$  - total number of workdays (workdays/ $\tau$ ),  $C_s$  - projected effective working hours per shift (h/shift),  $z_i$  - total number of production workers (workers/ $\tau$ ),  $p_{ni}$  - average norm-hour execution for the

observed organizational unit and time period,  $\eta_{ri}$  - productive human resources utilization level.

**Table 2.** Input data for defining the mathematical model

By analyzing the trend of the achieved production over a period of five years, respecting the average values, minimum and maximum constraints were determined (Table 2, columns 2 and 3). In Table 2, column 4 shows the elements of matrix C, Relation (1).

Due to limited space the coefficients  $a_{ij}$  in Objective:

$$\max F(x) = 0,51203x_1 + 0,28x_2 + 0,35x_3 + \dots + 2,203x_{16} + \dots + 5,4215x_{40} + 3,5x_{41} \quad (6)$$

Production human resource constraint  $j = \overline{1,6}$ :

$$\begin{aligned} 0,017409x_1 + 0,00896x_2 + 0,021x_3 + \dots + 0,173488x_{40} + 0,112x_{41} &\leq 135166 \\ 0,087045x_1 + 0,0448x_2 + 0,0805x_3 + \dots + 0,742745x_{40} + 0,4795x_{41} &\leq 320987 \\ 0,095238x_1 + 0,0532x_2 + 0,06545x_3 + \dots + 1,116829x_{40} + 0,721x_{41} &\leq 398879 \\ 0,06554x_1 + 0,0434x_2 + 0,06755x_3 + \dots + 0,623472x_{40} + 0,4025x_{41} &\leq 63628 \\ 0,186891x_1 + 0,10444x_2 + 0,07x_3 + \dots + 2,087278x_{40} + 1,3475x_{41} &\leq 363549 \\ 0,059907x_1 + 0,0252x_2 + 0,0455x_3 + \dots + 0,677688x_{40} + 0,4375x_{41} &\leq 121457 \end{aligned} \quad (7)$$

Market constraints  $j = \overline{7,88}$ :

$$\begin{aligned} x_1 \leq 18000; x_2 \leq 5000; x_3 \leq 17000; \dots x_{40} \leq 1000; x_{41} \leq 350; \\ x_1 \geq 5000; x_2 \geq 500; x_3 \geq 5000; \dots x_{40} \geq 90; x_{41} \geq 30; \end{aligned} \quad (8)$$

### 3. Results and Discussion

To secure optimal solutions, the use of various software tools can be employed (Grenci, 2022; Cecílio & dos Santos, 2018). In this paper, a program written in the Mathematica software package is used. The program is designed to provide not only optimal solutions at the output (Relation (9)) but also a capacity analysis (Table 3) that indicates the presence of unrealistic constraints and unused capacities. The optimal production program engages 525236 h/year, which represents 37,42 % of the available human resources potential of 1403666 h/year.

Degree of engagement of the workforce at the level  $S_i$ :  $S_1$  - 14,84%,  $S_2$  - 24,83%,  $S_3$  - 27,29%,  $S_4$  - 100%,  $S_5$  - 53,51%,  $S_6$  - 48,11%.

the mathematical model are not shown in the paper.

The mathematical model for optimizing the production program from the aspect of maximizing the use of available workforce capacities by subsystems  $S_i$  while respecting market constraints has the following form, Relations (6-8):

**Table 3.** Part of the results of capacity analysis

$$\{525236, \{x_1 \rightarrow 5000, x_2 \rightarrow 500, x_3 \rightarrow 5000, x_4 \rightarrow 7000, x_5 \rightarrow 200, x_6 \rightarrow 9000, x_7 \rightarrow 10000, x_8 \rightarrow 12000, x_9 \rightarrow 40000, x_{10} \rightarrow 21500, x_{11} \rightarrow 17000, x_{12} \rightarrow 50000, x_{13} \rightarrow 300, x_{14} \rightarrow 700, x_{15} \rightarrow 1000, x_{16} \rightarrow 100, x_{17} \rightarrow 800, x_{18} \rightarrow 900, x_{19} \rightarrow 4500, x_{20} \rightarrow 35600, x_{21} \rightarrow 35600, x_{22} \rightarrow 3000, x_{23} \rightarrow 500, x_{24} \rightarrow 1600, x_{25} \rightarrow 500, x_{26} \rightarrow 700, x_{27} \rightarrow 30, x_{28} \rightarrow 3000, x_{29} \rightarrow 20000, x_{30} \rightarrow 200, x_{31} \rightarrow 70, x_{32} \rightarrow 70, x_{33} \rightarrow 70, x_{34} \rightarrow 120, x_{35} \rightarrow 700, x_{36} \rightarrow 3929, x_{37} \rightarrow 600, x_{38} \rightarrow 30, x_{39} \rightarrow 300, x_{40} \rightarrow 90, x_{41} \rightarrow 30\}\} \quad (9)$$

#### 4. Conclusion

By applying simulation and optimization processes, it can be concluded that it is necessary to redistribute production human resources in order to increase the utilization rate of the workforce with the optimal production program. The optimal production

program engages 525236 h/year, which represents 37,42 % of the available human resources potential of 1403666 h/year. Since the established model has "surpluses" of capacity, it is necessary to redistribute the production of human resources in order to increase the degree of engagement of the available workforce.

## THE NEW MULTICRITERIA-BASED MODEL FOR QUALITY ASSESSMENT OF WRITTEN MEDIA MESSAGES - PERSPECTIVES FOR APPLICATION

**Abstract:** *Media messages are any form of communication delivered to the audience, broadcasted in written, oral or visual form. They may include TV shows, web pages, advertisements, news stories, blogs or social media posts, inter alia. At present, facts are no longer the paradigm of journalism. They are often replaced by short messages constructed on the basis of biased or emotional content. In addition, commercial value of news and digitization of resources have also changed the formation of texts and images. They are built using entries posted on Facebook or Twitter (often by fake accounts), instead of face-to-face interviews, participant observation, or citing primary sources and opinions. On the other hand, there are numerous discussions on the quality of data and information, also in the context of journalism. Although there is no agreement whatsoever as to the factors contributing to high-quality communication, the author attempts to demonstrate a new model for quality assessment of written media messages. It comprises four main groups of quality factors, namely: 1) information, 2) linguistic, 3) publishing, and 4) useability. Each group consists of specific criteria, which are analyzed with respect to different media content. Its potential of application for quality assessment of press and social media will be discussed.*

**Keywords:** *media messages, quality assessment, quality of journalism, multicriteria model*

### 1. Introduction

The contemporary world is characterized by a wide variety of messages and their providers (senders). Paradoxically, the phenomenon of online loneliness is observed in the information noise, and social media often create isolating media bubbles. On the other hand, in the practice of large newsrooms, perfectly optimized content is

displayed by a large number of users. "Reach" journalists, or rather "media workers", can guess the audience's needs on their own, or being supported by artificial intelligence (AI), i.e. they can anticipate their enthusiasm or irritation. This process has intensified in the last decade.

AI, which is used more and more commonly in the news making process, does not protect the originality of opinions and the

Email: [dariusz.ras@upjp2.edu.pl](mailto:dariusz.ras@upjp2.edu.pl)

truthfulness of information. The most important thing is the clickability of the material. Click-through rate is a big nuisance for many contemporary journalists, which makes it necessary to prepare the material in advance, with the content of keywords best targeted at the tastes of the target audience, and most often omitting issues such as reliability, non-conformity, and sometimes even human dignity. Many observers believe that with further intensification of this process, tools such as ChatGPT will soon displace people from the creative process in the media. Click-through rate as a criterion will become the most important factor in evaluating the communication processes.

Therefore, the selection of information and opinions becomes a serious problem, not because of the “loudness” of the title and the emotions it evokes, but because of their internal quality: consistency, reliability, originality, journalistic sovereignty of thinking, social commitment, concern for the common goodness, creative attitude towards the work performed, etc. That is why this paper is looking for a multi-criteria measure of journalistic quality, a method that will indicate content that is worth following and then recommending to the audience both in real life and online. Although the dependence on intelligent technologies in communication is huge nowadays, it is necessary to reflect on the quality of journalism, and not only on the perfectly optimized and “clickable” content.

In the literature, a lot of space has been devoted to research on the quality of journalistic messages. As quality is a multidimensional concept, these are usually interdisciplinary projects, covering areas such as quantitative and qualitative content analysis, linguistics, multi-criteria analysis, data mining and many others (Raś 2023). The aim of this research is to demonstrate a new model for assessing the quality of press articles and the possibilities of its application to different types of press materials.

## 2. State-of-the-art knowledge on the quality of media messages

The literature on the quality assessment of media messages can be categorized in two main groups. First of them refers to the factors revolving around “quality journalism”, which is defined as “journalistic excellence” and described by values such as i.a. truth/facticity, 2) relevance/context, and 3) independence. However, these factors are multidimensional; for example, truth/facticity consists of diversity, transparency, interactivity and clarity of language and style (Meier 2019).

The second group of research papers refers to content quality assessment (CQA) based on the pre-established criteria. For example, Chai *et al.* (2010) provides a CQA framework for social media. It consists of Information Quality (IQ) dimensions which comprise factors such as i.a. *user feedback, amount of data, reputation, objectivity, relevancy, reliability, completeness, accuracy, timeliness, understandability, value-added, consistency, security and accessibility.*

Similar criteria may be also found in other, non-media contexts such as data quality assessment and the meaning of quality for data consumers. One of the first research attempts in this area was undertaken by Wang and Guarascio (1991), who identified 20 data quality attributes. This model was elaborated in the subsequent publications by Wand and Wang (1996) and Wand and Strong (2015), *inter alia*. The quality attributes distinguished by this group of researchers have been selectively used in studies related to the quality of databases and information systems.

According to Batini *et al.* (2009), they provided several important classifications of data quality criteria, allowing to distinguish a set of four key attributes most commonly described in the literature. They include:

*accuracy, completeness, consistency, and timeliness.* Other studies such as the report by DAMA (2003) described six criteria for assessing the quality of information in databases, calling them *basic* (primary). In addition to the four above, they distinguished *uniqueness* and *validity*. Additional features mentioned in this report include usability, flexibility, trust in data and data value. Sidi *et al.* (2012) additionally distinguished, on the basis of the literature review, over 20 additional data quality dimensions, including *accessibility, availability, security, effectiveness, efficiency, reliability, objectivity* and *ease of use*. The literature does not provide a universal set of data quality dimensions. Multiple discrepancies in types and definitions of the quality characteristics are due to the contextual nature of data quality.

As regards the quality criteria (QC) of written media messages specifically, little research has been done in this area. Pulikowski (2007) developed a framework for assessing Internet documents, which consists of two fundamental criteria: *usability* and *reliability*. The usability criterion is explained by *content* and *timeliness*, while reliability - by *authorship, goals, objectivity (impartiality)* and *correctness*. Although it can be useful in assessing some media messages, this model is insufficient to assess press releases, especially coming from the newspapers.

Comparing the quality of messages with a homogeneous thematic context, especially in the context of the press or Internet content, becomes necessary considering the contemporary tools, such as AI, supporting (or replacing sometimes) journalistic work. It seems necessary to verify such “artificial” outcomes. In response to this research gap, the study was conducted to develop a new, versatile, multicriteria-based framework for assessment of written media messages published in printed and online form.

## 3. Model and methodology

### 3.1. Building the model

The new model has been developed based on the thorough review of literature and preliminary tests on newspaper articles dated from 1865 to 2023. It has a hierarchical structure consisting of four fundamental quality dimensions: *Information, Linguistic, Publishing* and *Useability* (**Figure 1**).

**Informational quality** consists of seven criteria: *timeliness, accuracy, reliability, credibility, consistency, uniqueness, and completeness.* *Timeliness* refers to the question whether the press material appeared at the time of the event or contains information current as of the date of its publication. *Accuracy* indicates that content of the material contains details showing or describing the actual state of the event in question. *Reliability* means that the information in the press release is supported by appropriate and properly cited sources of information, either from a clearly identified and cited source or from a witness. *Credibility* indicates that the information comes from a reliable source and/or author. *Consistency* shows whether the press material is internally consistent and does not contain contradictory information. As regards *uniqueness*, it refers to unnecessary duplication of information inside a given material and/or across other press messages released at the same time. Finally, *completeness* is to measure whether the material properly explores a given topic in relation to the press genre it represents.

**Linguistic quality** comprises three criteria: *concise, readability and beauty of the language.* *Concise* means that the press material contains the right amount of information in relation to the genre it represents and the topic addressed. It refers to the so-called economy of the message, or its appropriate level of condensation. *Readability* defines the correctness in terms

of language and style, lack of different errors, and the proper organization of the content. *Beauty of the language* reflects the aesthetics of the text, which can be the source of so-called “aesthetic pleasure” for the reader.

**Publishing quality** consists of three characteristics: objectivity, relevance and attractiveness. *Objectivity* is a multidimensional criterion, indicating that the material clearly separates facts from opinions and its content is balanced. Based on its reading, it is impossible to notice any likes, worldviews and/or interests of the author. *Relevance* shows the matching of the content and headline to the press genre and nature of the event. *Attractiveness* means that the material (its content, title and lead) attracts the recipient's attention and makes them want to read it.

**Useability** is the quality dimension consisting of two features: *usefulness* and *availability*. *Usefulness* indicates that the

material contains information useful in some way to the recipient and/or sender and their decision-making processes. *Availability* shows the easiness of the material to obtain, retrieve and analyze.

### 3.2. Deriving weights using PC method

The application of the above model in assessment of media messages requires prioritization of QC. There are numerous multicriteria-based methods used to derive weights and produce relevant ranking of alternatives. One of them is the analytic hierarchy process, a PC-based (pairwise comparison) tool which allows analysis of complex hierarchical structures (eg. Kułakowski 2020). This method starts from building a hierarchical model (as shown in Figure 1), which is divided into groups of parent-children criteria, and analyzed using a 9-point, fundamental scale enabling comparison of two alternatives at a time.

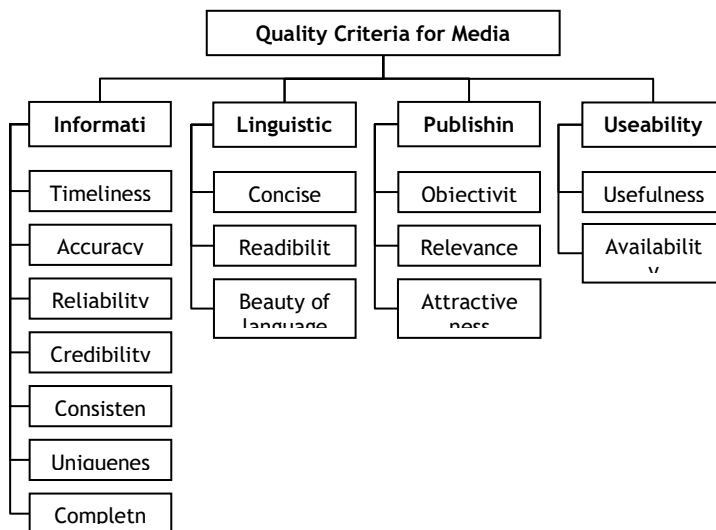

Figure 1. QAC for media messages

Assuming two elements being compared, *A* and *B*, the respondent has the following possibilities:

- *A* and *B* are equally important (value of intensity: *I*),
- *A* is of moderate importance over *B* (or: *B* over *A*) (3),
- *A* is of strong importance over *B* (or: *B* over *A*) (5),
- *A* is of very strong (essential) importance over *B* (or: *B* over *A*) (7),
- *A* is of absolute (extreme) importance over *B* (or: *B* over *A*) (9),
- intermediate values (2, 4, 6, 8) used if dominance of one alternative over another fits in somewhere between scale degrees of 1, 3, 5, 7 and 9.

Results of the comparisons are introduced into the *PC* matrix, which is always a square matrix with “1” in diagonal (an element compared with itself has always “the same importance”). All the entries above the main diagonal are the reciprocals of the entries below the diagonal (Table 1).

**Table 1.** Example of *PC* matrix

	A	B	C	D
A	1	3	1/3	7
B	3	1	8	5
C	1/3	1/8	1	3
D	1/7	1/5	1/3	1

The *PC* matrix allows us to derive the ranking vector of priorities (weights), which sums up to one:

$$w = [w_1, w_2, w_3, \dots, w_n]$$

The analysis can be performed using a number of prioritization procedures, such as eigenvector (*EV*), geometric mean (*GM*) or arithmetic mean (*AM*) method (Prusak 2017). In addition, each *PC* matrix should be tested for consistency based on the following formula:

$$CI = \frac{\lambda_{max} - n}{n - 1}$$

where *CI* is Consistency Index,  $\lambda_{max}$  is the largest eigenvalue of the matrix, and *n* is the number of alternatives in a group being compared against each other. The final Consistency Ratio (*CR*) is calculated by dividing *CI* by the so-called random index (*RI*):

$$CR = \frac{CI}{RI}$$

where *RI* is a fixed, tabulated value for *n* = 3, ..., 15. For example, for *n*=4, *RI*=0,86. A matrix is consistent for *CR*<0,10, otherwise it is inconsistent and the judgments should be modified or repeated (eg. Vargas 2008).

For consistent results one can calculate the so-called global priorities. In multi-level hierarchies, global values are calculated as multiplication of weights of the main (parent) criteria and their (children) subcriteria. Additionally, if *PCs* are made by a group of respondents, the priorities (weights) derived for each of them can be aggregated into a common vector (Prusak and Stefanów 2014).

## 4. Results and discussion

As the AHP is an expert method (experts are individuals whose opinions can be used for final recommendations), three experts (two academic and one practitioner) in the area of journalism and media research were selected to evaluate the hierarchical model. The results were aggregated using a geometric mean method and presented as a percentage values in Table 2 and Table 3.

**Table 2.** Priorities for quality domains

Domain	Priority
Informational	0,3501 (35,01%)
Linguistic	0,1373 (13,73%)
Publishing	0,2298 (22,98%)
Useability	0,2827 (28,27%)

**Table 3.** Priorities for quality criteria (QC)

QC	Local	Global
Timeliness	0,0764	3,39%
Accuracy	0,2511	10,31%
Reliability	0,1941	5,49%
Credibility	0,2778	9,83%
Consistency	0,0742	2,19%
Uniqueness	0,0619	2,03%
Completeness	0,0645	1,76%
Concise	0,3515	4,52%
Readability	0,4675	7,24%
Beauty of language	0,1810	1,97%
Objectivity	0,7117	15,70%
Relevance	0,1777	4,24%
Attractiveness	0,1105	3,05%
Usefulness	0,7806	23,38%
Availability	0,2194	4,89%

The analysis shows that the matrices were highly consistent for all the experts, with CR ranging from 0,00 to 0,09. In one case CR=0,20, but after additional considerations it was accepted for further analysis as the inconsistency was at tolerable level (Wedley 1993). The priorities derived for quality domains clearly indicate that *Information* is the most important feature in quality assessment of media messages ( $w=35,01\%$ ), followed by *Useability* ( $w=28,27\%$ ). Within the domain of *Informational quality*, the most important QC is *credibility* ( $w=27,78\%$ ), and within the *Linguistic* domain, *readability* received the highest priority value ( $w=46,75\%$ ). As regards global QC ranking, *usefulness* and *objectivity* contribute the most to the quality analysis of media messages with priority values of 23,38% and 15,70%, respectively. It was followed by *accuracy* ( $w=10,31\%$ ) and almost equally significant *credibility* ( $w=9,83\%$ ). Such results can be explained by the common attitude towards practicality, usefulness, usability and information accuracy (which sums up to 38.58%). News regarding the daily weather forecast supports the recipient in choosing appropriate clothes. The media shows the public debates and

periodically supports electoral decisions at various levels of government, and provides economic information which supports customers in their decisions on a daily basis. It is also not surprising that the desired attitude towards objectivity and credibility of messages is observed (25.53% in total), which in everyday life is associated with authenticity and truthfulness, most often with regard to the collected information and its impartial representation. The key element here is a credible source of information, on the basis of which a multilateral or multifaceted opinion on a given topic is provided. Nowadays, access to the possibilities of creating information is almost unlimited, and some of it can simply be written with the use of “poisoned sources”. Therefore, in qualitative analyzes these four aspects of the assessment are strongly emphasized, which together account for almost 2/3 of the importance (64.11%) of written journalistic texts.

## 5. Conclusions and implications

The objective of the current research was to develop and demonstrate the analysis of a new, multicriteria-based framework for assessment of written media messages published in printed and online form. The model can be further employed to assess a number of press materials. As it would be difficult to use AHP for such an analysis (due to a limited number of PCs that can be performed effectively), each criterion can be operationalised using eg. five questions for “yes” or “no” answers. It would allow using another multicriteria analysis (ia. TOPSIS) to objectively rank the selected materials according to their quality.

New tools supporting the work of the media, such as ChatGPT, will probably gain more and more importance due to the generated click-through rate and usefulness of their materials. However, the increase in the

number of press releases generated by AI benefits primarily online aggregators and large technology platforms that have access to a wide range of information consumers. Such a complicated and rapidly changing world of written media messages needs deep quality-related narratives that will explain this complexity.

The research on the quality of written messages offers a protection tool, under

which publicists and journalists will still be able to reveal the secrets of people in power, politics, economy, judiciary, public administration, in the name of independence and journalistic quality. Click-through rate, however, cannot become the only or the most important criterion for evaluating information and opinion-forming messages.

## ASSESSMENT OF SERVICE QUALITY USING SYNERGIES OF FUZZY SERVQUAL, FUZZY KANO'S MODEL, AND FUZZY ANALYTIC NETWORK PROCESS INTO QFD

**Abstract:** *The essence of banking service will always be service quality. To gain customer satisfaction, enhance market rivalry, and achieve sustainable performance. The primary goal of this article is to identify the primary factor contributing to high customer dissatisfaction and poor service quality in bank services. This article synergies fuzzy SERVQUAL, fuzzy Kano model, and fuzzy analytic network processing into QFD. Structured survey questions based on SERVQUAL and Kano models were developed and disseminated to collect data. According to the findings, the bank should offer the promised service within the time range, respond to client concerns immediately, and supply appropriate service within the time frame. Furthermore, an employee should give timely care to the client; the employee should never be too busy to respond to customer demands and inform the consumer when service is delivered. In conclusion, focusing on customer requirements can enhance the bank's service level, which increases customer satisfaction.*

**Keywords:** *Customer Satisfaction, Fuzzy SERVQUAL Model, Fuzzy Kano's Model, Fuzzy ANP, QFD, Service Quality*

### 1. Introduction

In today's competitive market, businesses lose customers owing to the poor quality of services or products they provide (Tsfaye, 2015). Meanwhile, the primary reason for client loss is that service providers frequently fail to adequately comprehend their customers' expectations, resulting in dissatisfaction with the service they receive. However, to overcome these issues, service providers must focus on customer service (Berushie, 2014). Hence, "the longer a customer stays with a bank, the more utility the customer generates" (Kebede, 2017). According to Basari & Shamsudin (2020); Hamzah & Shamsudin (2020); and Ilias & Shamsudin (2020), customers recreate a

significant persona in business performance. In line with this, customer satisfaction increases as the quality of services/products offered by the firm advances (Hasfar et al., 2020).

Johnston & Clark (2001), cited in Goldstein et al., (2002), define and pinpoint the concept of services in the following ways: Services operations: a method of extrading services; services experiences: the client directly uses the services; services outcomes: the welfare and success of the services; the value of the services: the benefits the client perceived to be inherent in the service's consideration of the service's cost. Furthermore, Grönroos (2001) defines the service concept as "an idea of how the quality-generating resource should function

---

Corresponding author: Getahun Mekuria  
Email: [getahunmekuria3@gmail.com](mailto:getahunmekuria3@gmail.com)

and what result they should achieve for the customer." On the other hand, Hernon & Nitecki (2001) define service quality from a different perspective; these include excellence, value, conformance to specification, and meeting or exceeding expectations. Also, Ramya et al., (2019) describe service quality as the capacity of a service provider to satisfy clients in a way that improves its commercial performance. The services sector encompasses a diverse and complex range of businesses and initiatives. Subsequently, Ghobadian et al., (1994) sort the services sector into three categories: national and local government, which includes areas like education, health, social security, police, military, transport, legal, information, and credits; non-profit private services, which includes institutions like charities and churches; mutual societies and art foundations; and for-profit private services, which includes utilities, hotels, airlines, architects, restaurants, solicitors, retailers, entertainment, banks, insurance companies, advertising agencies, consulting firms, market research companies, and communications. In short, several different types of research were done to determine what aspects affect service quality in the banking industry. For example, Gebre (2017) primary causes of poor service quality in the banking services sector are a lack of customer database management and inadequate infrastructure and technology. Furthermore, "employee competence and skills, the reliability of the electronic system, the reliability of the service system, the impeccability of the banking system's integrity, and the accountability instrument were among the other factors that affected the excellence of service quality of the bank services" (Pourmohammad et al., 2016). However, despite extensive research on the many facets of service quality, no study provides solid advice on how customer-oriented service businesses could raise customer satisfaction by combining various

quality measurement tools with customer-oriented approaches. Therefore, this article uses an optimal decision framework for bank services based on the synergies of fuzzy SERVQUAL, fuzzy Kano's model, and fuzzy analytic network processing into the QFD model.

## 2. Literature Review

### 2.1 Service Quality

Concepts of service quality have been contested for centuries and are still a prominent area of study today. In many academic works of literature, service quality is also primarily defined in terms of the superiority of the service (Gera et al., 2017; Marković et al., 2015). Harvey & Green (1993) summarized quality into two distinct relative concepts: first, quality has multiple meanings for different individuals, and second, quality is related to "process" or "outcomes." As a result, they reflected exceptional quality, fitness for purpose, value for money, and transformative. Considering this, the concept of quality leads to a meeting between what customers expect and perceive (Saghier & Nathan, 2013). Ghobadian et al., (1994) categorized the definition of quality into five broad categories based on how crucial they are to service businesses, including transcendence, product, process or supply, customer, and value approaches. While Mackay & Crompton (1990) defined service quality as "the relationship between what customers desire from a service and what they perceive that they receive." On the other hand, Lenka et al., (2009) specified that service quality is the discrepancy between customer expectations and perceived service. Accordingly, Elmayer (2011) defines the degree of service quality from the customer's perspective, and there is a relationship between anticipated and perceived service quality. Likewise, Sawant (2016) defines

service quality as "the overall assessment of service by the customer." Ali (2018) stated that definitions of service quality differ and are subject to various models, customer expectations, and satisfaction. Following that, Gupta et al., (2018) defined service quality as "the consumer's level of satisfaction from the service encounter; the consumer's expectations before taking the service; and how the service is conveyed concurrently." Satisfaction, in particular, is the result of a correlation between consumers' expectations and their views of the service's implementation (Shayestehfar & Yazdani, 2018). Furthermore, meeting or exceeding customers' service requirements will result in higher service quality and customer satisfaction (Uppal, 2019). Given that customer expectations are influenced by their perceptions of a company's image, and corporate image is the outcome of how customers perceive a company, improving the technical and functional quality of service by businesses increases customer satisfaction (Gronroos, 1984). Furthermore, there are two categories of service quality: first, "how" the service is delivered, and second, "what" the final perception of the customer is (Brady & Cronin, 2001; Kang, 2006). Also, Zameer et al., (2015) define a corporate image as "the perception about the organization that the customer holds in their memories." Venetis & Ghauri (2004), currently, operating service businesses consider service quality to be a significant success element; in general, two main mechanisms explain the influence of service quality on profitability: first, service quality is considered a way for service differentiation and competitive advantage to attract new customers and increase market share, and second, service quality is becoming a way for customer retention. Also, Ravichandran et al., (2001) indicated that several techniques were devised to keep customers, but the crux was to improve service quality. Moreover, Sigit Parawansa

(2015) stated that customer retention has four main stages, known as "the four-stage model of loyalty power," such as cognitive loyalty, affective loyalty, conative loyalty, and action loyalty. Service quality is remarkably relevant for the banking industry, as customers typically look for the service they perceive. Successful bank firms prioritize offering higher-quality service than their competitors. Likewise, quality of service is the principal determinant by which banks can invite new customers and helps to retain existing customers (Ahmed, 2017). Service quality has become a critical determinant for every business's survival and competitiveness (Hu et al., 2009). Therefore, service companies should plan, organize, implement, and control the quality system to meet or exceed customer expectations and increase customer satisfaction (Ramdhani et al., 2011). As a further significant causal aspect of company competitiveness, service quality is seen to have a direct bearing on firm costs and profits (Gounaris et al., 2003; Gupta et al., 2018).

## 2.2 Customer Satisfaction

Customer satisfaction has been a popular subject in marketing and academic research. (Cengiz, 2010; Chiguvu et al., 2017; Kombo, 2015; Murugiah & Akgam, 2015; Narteh & Kuada, 2014; Ozatac et al., 2016); and others are examples. Subsequently, Gunasekare (2016) states that "customer satisfaction is a set of feelings or outcomes attached to a customer's experience with any product or service." But nowadays, consumer happiness is a significant precursor to client retention and returning business (Syed, 2019). Also, Hanif et al., (2010) explained that in the telecommunications service sector, if a company wants to be profitable in the long run, it must satisfy its customers by crediting fair tariffs and high customer service, thereby dominating the market. On the other hand, Vásquez et al., (2017) explained that

measuring customer service satisfaction is a method that should be chronic in any company so that they can control the processes and activities executed to enhance their performance. Furthermore, a hospital is a significant healthcare provider and must acknowledge the value of patients' choices; patients call the hospital seeking relevant, high-quality medical care, a safe environment, and moderately sufficient facilities (Singh, 2012). Meanwhile, Manzoor et al., (2019) stated that patient satisfaction is noted as a touchstone to assess the potency of health services given in the hospital. Furthermore, the hotel is a primary hospitality industry and provides customer-confined service. In line with this, the hospitality industry's service sectors must put the customer need first to remain competitive and establish a name for themselves in the market (Pazir & Amin, 2015). Likewise, Luturlean & Anggadwita (2015) highlighted how businesses could use the customer experience management approach to keep customers and increase the intention to revisit. Nevertheless, in the banking service sector, the main component of customer satisfaction is the correlation between the customer, the service provider, and the service they perceive (Saghier & Nathan, 2013). Besides, Bena (2010) discovered two key issues: the criteria for assessing client happiness must be defined first, according to the field of business and the firm's requirements, and second, clients prefer to declare they are pleased or select an indecisive response. Therefore, to compete in the global market, any organization must put customer satisfaction before company profits and other operations. Similarly, customer satisfaction is critical for the continued success of any business (Mekonen et al., 2019). Customer satisfaction is a significant concern for all companies to enhance customer loyalty and design more reliable business performance (Grønholdt et al., 2000). Further, Munusamy et al., (2010)

define customer satisfaction as "global issues that affect all organizations, regardless of their size, whether profit or non-profit, local or multinational." As, Lenka et al., (2009) explained, customer satisfaction is a synergy of their cognitive and affective responses to the service encounter.

### **2.3 Quality Measurement Tools for Customer-Oriented Approaches**

Giannikas et al., (2019) assert that "customer orientation concerns the degree to which an organization focuses on the customer, recognizes their desires and places meeting their needs as a foremost priority." According to previous study findings, the impact of customer orientation, including value-based customer orientation, may be described in terms of two factors connected directly to customer satisfaction Wang et al., (2012) and action-based customer orientation (H. He & Li, 2011). Also, value-based concerns meet customer demand by being aware of the customer's expectations for service quality, which can determine customer satisfaction (Blocke et al., 2011). While action-based approaches emphasize utilizing customer feedback and accommodating it when making organizational choices (Y. He et al., 2011). Accordingly, Dragolea & Ungureanu (2008) explain how an organization's success depends on its capacity to control customer expectations while promoting investment and loyalty. Consequently, to keep its current customers, every organization needs to be customer-centric and open to hearing what they have to say.

#### **2.3.1 SERVQUAL Model**

Several research publications cover the theoretical and practical use of SERVQUAL in a wide range of industrial, business, and non-profit organizations. For example, in the healthcare sector (Anbari et al., 2014; Umath

et al., 2015), higher education (Galeeva, 2016; Ulewicz, 2014), tourism service (Home, 2006), restaurant (Lee & Hing, 1995; Yu-qiang & Jun-jia, 2011), bank (Ilyas et al., 2013; Lau et al., 2013), telecommunication (Alnsour et al., 2014), apparel retail (Bhaskar & Shekha, 2011), public service (Bryslan & Curry, 2001), local government (Donnelly et al., 1995), electronic commerce B2C (Alzola &

Robaina, 2005), business – to – business service (Mehta & Durvasula, 1998), technical and vocational colleges (Akhlaghi et al., 2012) and more. Further, SERVQUAL has a variety of potential applications; it can assist service and retail firms in assessing customer expectations and perceptions of service quality, as SERVQUAL has five universal dimensions (Parasuraman et al., 1988).

**Table 1.** Essential dimensions of service quality

SERVQUAL dimensions	Definitions	Source
Tangible	Physical facilities, equipment, and appearance of personnel.	Parasuraman et al., (1988)
Reliability	Ability to perform the promised service dependably and accurately.	
Responsiveness	Willing to help customers and provide prompt service.	
Assurance	Knowledge and courtesy of employees and their ability to inspire trust and confidence.	
Empathy	Carrying, individualized attention the firm provides its customer.	

SERVQUAL reports respondent responses on their expectations and perceptions of service quality (Prakasha & Mohanty, 2012). Moreover, SERVQUAL contains 22 items (Likert-type) with five dimensions, so each item in the SERVQUAL tool is of two classes: one to measure expectations and, thereby, firms overall within a business, and the second to measure perceptions about the particular company (Mohd. Adil et al., 2013). Accordingly, Robinson (1999) claims that the difference between the two findings provides a gauge for the discrepancy between expectations and perceived service quality, which is performance minus expectations. Following that, for the particular respondent, the service quality for each dimension is determined as follows:

$$SQ_j = \sum_{i=1}^{n_j} \frac{P_{ij} - E_{ij}}{n_j} \quad (1)$$

Where

$SQ_j$  = service quality of dimensions

$E_{ij}$  = expectations of the firms for item  $i$  in dimension  $j$

$P_{ij}$  = perceived performance of the form on item  $i$  in dimension  $j$

$n_j$  = number of items in dimension  $j$ .

However, despite its widespread usage and popularity, SERVQUAL has received several philosophical and practical objections. See, for example: (Babakus & Boller, 1992; Bolton & Drew, 1991; Boulding et al., 1993; Cronin & Taylor, 1992; Genestre & Herbig, 1996; Teas, 1993) As a result, Buttle (1996) categorizes the critiques into two parts: one theoretical (paradigmatic objections, gaps model, process orientation, and dimensionality) and one operational (expectations, item composition, a moment of truth (MOT), polarity, scale points, too much administrative work, and variance extracted).

2.3.2 Kano's Model

Doctor Noriaki Kano, a Tokyo professor, created the Kano model in 1984 to define service quality based on customer satisfaction (Seyedi et al., 2012). In the meantime, customer satisfaction is a one-dimensional operation, implying that the higher the perceived service quality, the higher the customer satisfaction (Kazemi et al., 2013). Perhaps, fulfilling the customer's request does not result in a higher degree of satisfaction from the customer (Mostafa et al., 2013). Based on the Kano model, customer needs were categorized into three phases: basic, performance, and excitement needs (Bhattacharyya & Rahman, 2004).

Similarly, Five kinds of customer satisfaction with a quality attribute exist, such as "must be," "one – dimensional," "attractive," "indifferent," and "reverse" Kurt & Atrek (2012); Lin et al., (2017), and the quality attribute is defined as shown in table 2.

Figure 1. Kano's model.  
 Source: Bhattacharyya & Rahman (2004)

Table 2. Categories Kano's model of quality attributes

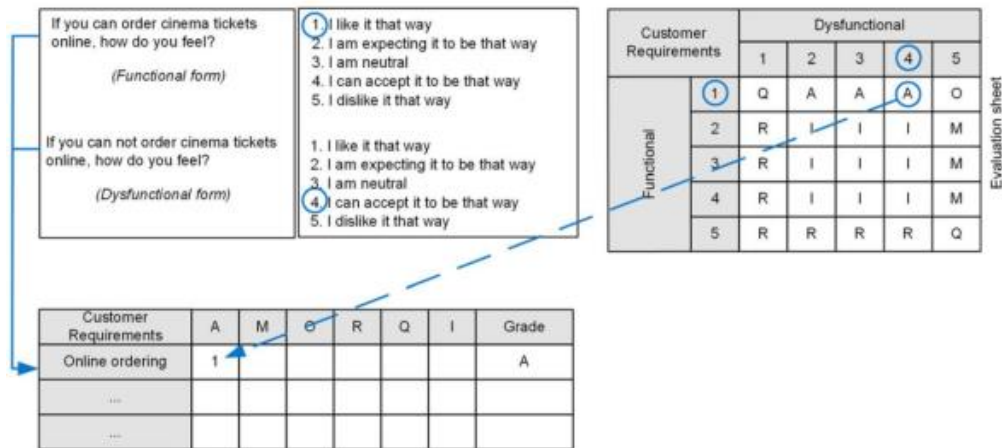

Quality attribute	Definitions	Source
Must – be	“Sufficient quality attributes <i>do not</i> lead to customer satisfaction but insufficient quality attributes lead to customer dissatisfaction.”	(Kurt & Atrek, 2012; Lin et al., 2017)
One – dimensional	“Sufficient quality attributes lead to customer satisfaction but insufficient quality attributes <i>do not</i> lead to customer dissatisfaction.”	
Attractive	“Sufficient quality attribute leads to customer satisfaction but insufficient quality attributes <i>do not</i> lead to customer dissatisfaction.”	
Indifferent	“Sufficient quality attributes <i>do not</i> lead to customer satisfaction and insufficient quality attributes <i>do not</i> lead to customer dissatisfaction.”	
Reverse	“Sufficient quality attributes lead to customer dissatisfaction and insufficient quality attributes lead to customer dissatisfaction.”	

Likewise, to categorize requirements or quality attributes, it is necessary to use Kano's questionnaires, which are sorted into two types, i.e., functional and dysfunctional forms of questions. See, for example, the figure 2 (Madzik et al., pp. 3, 2019).

Numerous research papers consolidate the application of Kano's model in an

assortment of industrial, profit, and non-profit firms (table 3).

But, regardless of the numerous benefits of Kano's model, it may have been criticized for a case in which, Gregory & Parsa, pp -40 (2013) include lengthy questionnaires that exclude the quantitative or qualitative performance of the specific attributes.

**Figure 2.** Categorization of a requirement using the Kano approach.

### 2.3.3 Quality Function Deployment (QFD)

Bouchereau & Rowlands (2000) define QFD as “a visual connective process that helps teams focus on the needs of the customer throughout the total development cycle.” Quality function deployment (QFD) is supported by a matrix approach to design

and function the essentials (commencing with customer requirement) upon the way of attaining them (Jagdev et al., 1997). As a result, a set of charts originated to show the connection between client expectations for service attributes and service planning. Likewise, “Quality Function Deployment (QFD) is a service planning and

development support method, which provides a structured way for service providers to assure quality and customer satisfaction while maintaining a sustainable competitive advantage” (Andronikidis et al., pp-320, 2009). The indicated usage of the QFD approach in many service areas demonstrates its universal applicability. Such as bank service (Purba et al., 2018), hospitality (hotel service) (Paryani et al., 2010), healthcare service (Dijkstra & Bij,

2002; Gremyr & Raharjo, 2013), utility service (Jahanzaib et al., 2016), design/build project (Pheng & Yeap, 2001), software product development (Haag et al., 1996; Thackeray & Van Treeck, 1990) and more. In light of this, numerous circumstances or significant aspects described in the illustration below are necessary to put into practice and advance QFD (Kathawala & Motwani, 1994).

**Figure 3.** The Three Components of QFD: A System Model. Source: Kathawala & Motwani (1994) Modified

Despite its popularity and widespread acceptance, quality function deployment is subject to numerous criticisms; see, for example, Wolniak, pp-16 (2018), who argue that it is not flexible, time-consuming, labor-intensive, only allows for qualitative data, and creates difficulties for collaboration within multidisciplinary teams; and Andronikidis et al., pp-321 (2009), who assume linear association within customer requirements and service attributes, impose a Poel (2007) critiques quality function deployment from a methodological aspect, which includes that "customer demands are product/service dependent, customer demand can not always be represented by a linear additive value function, individual customer preference cannot be translated into a collective customer preference ordering without violating a number of very reasonable conditions, the correlation between customer demand and engineering

characteristics is not always non-negative and constant, the relative importance of customer demand can not be uniformly translated into a relative importance of the engineering characteristics, and the meaning of tragedy values is unclear or disputable."

#### 2.4. Multi-Criteria Decision-Making Tools

Multi-criteria decision-making analysis (MCDA) was introduced as a subsection of operations research intended to assist in solving problems (Jato-Espino et al., 2014). Since then, numerous multi-criteria decision-making techniques have been introduced to use them for different service and manufacturing sectors (Kiker et al., 2005; Lahdelma et al., 2000; Løken, 2007; Słowiński, 1986; Tonietto & Carbonneau, 2004).

## 2.4.1 Analytic Network Process (ANP)

The analytic network process consists of similar attributes to the analytic hierarchy process, which includes simplicity, flexibility, and coincident implementation of qualitative and quantitative measures and can add ebullience to the judicial process. In addition, the analytic network process deals with every event, i.e., a network of criteria, sub-criteria, and alternatives; moreover, in the analytic network process, every component in the network can interplay with each other by any means (Kheybari et al., 2020). Likewise, Kheybari et al., (2020)

recapitulate the analytic network process in four main steps, such as:

Step1. Building a model and converting a problem into a topic network structure.

Step2. Formulating a pairwise comparison matrix and determining priority vectors.

Step3. Generating a supermatrix and converting it to a weighted supermatrix.

Step4. Selecting the best option.

Numerous research papers discuss the use of analytic network processing (ANP) in a variety of industrial, profit, and non-profit organizations (table 4).

**Table 4.** Analysis of the Application area of the Analytic Network Process (ANP)

Author & year	Description	Area
Galankashi et al., (2015)	Prioritizing green supplier selection criteria	Green supply chain
Çelebi et al., (2010)	Logistics management	Small electronic appliance manufacturer
Simwanda et al., (2020)	Modeling the drivers of urban land-use change	Urban development
Abdi (2012)	Product family formation & selection for configurability	Manufacturing system
Gheshlaghi et al., (2019)	GIS-based forest fire risk mapping	Environmental planning
Bayazit (2006)	Vendor selection decisions	Supply chain
Boateng et al., (2015)	Risk prioritization in mega projects	Project management
Cheng & Li (2004)	Contractor selection	Project management
Cheng & Li (2005)	Project selection	Construction management
Cooper et al., (2012)	Selection of a third-party logistics provider	Pharmaceutical company
Dabestani et al., (2017)	Evaluation and prioritization of service quality dimension	4 – star hotel
Farman et al., (2017)	Optimum cluster head selection	Wireless sensor network
Genevois et al., (2015)	Automatic teller machine deployment problem	Bank service sector
Godse et al., (2008)	Web service selection	Web service industry
Hasanzadeh et al., (2013)	Coastal oil jetties site selection	Oil production industry
S. H. Chen et al., (2004)	Enterprise partner selection	Vocational education
Jharkharia & Shankar (2007)	Selection of logistics service provider	Logistics
Meade & Presley (2002)	R&D project selection	Research & Development program
Mulebeke & Zheng (2006)	Software selection in product development	Manufacturing industry
Wu et al., (2012)	Porter's Five Force analysis	Strategic management
Zhu et al., (2010)	A portfolio-based analysis for green supplier management	Supply chain management
Zare et al., (2018)	Prioritizing shift work disorder	Hospital service

Despite its reputation and widespread use, ANP has been subjected to several theoretical and practical criticisms. For instance, the method's complexity, the length of the implementation, and the uncertainty in giving judgment, especially at the cluster level (Kadoić et al., 2017).

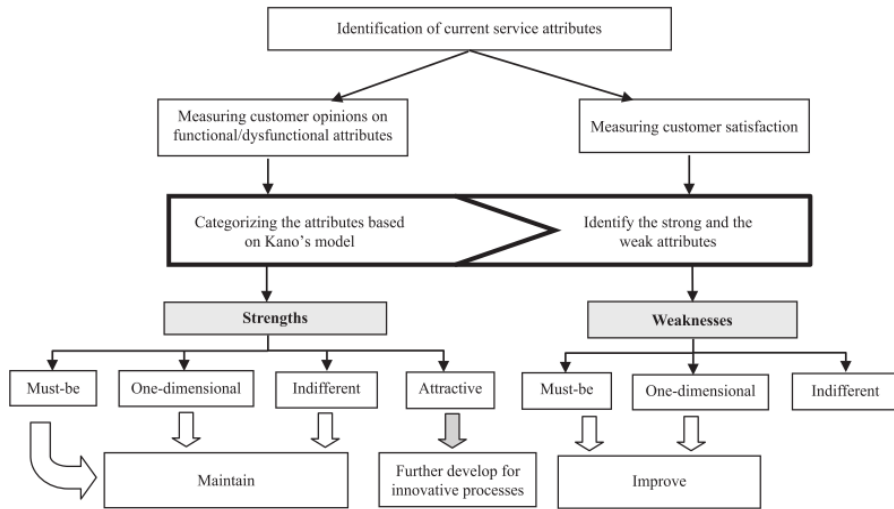

**2.5 Integration of Customer-Oriented Tools for Improving Service Quality**

In the current worldwide competitive market, it is not adequate for firms to depend exclusively on continuous improvement to sustain and advance their competitive advantage. The introduction of integrated customer-oriented tools for increasing service quality, similar to the synergy of changed processes, has been widely applied in many service and industrial businesses. See, for example, a fuzzy QFD approach using SERVQUAL and Kano models (in the case of hotel service) (Beheshtinia & Farzaneh Azad, 2017), integration of SERVQUAL and Kano models (in the case of airline service) (Basfirinci & Mitra, 2015), application of integration of Kano model, AHP technique and QFD matrix (case of banking service) (Pakizehkar et al., 2016); integration of Kano model and AHP

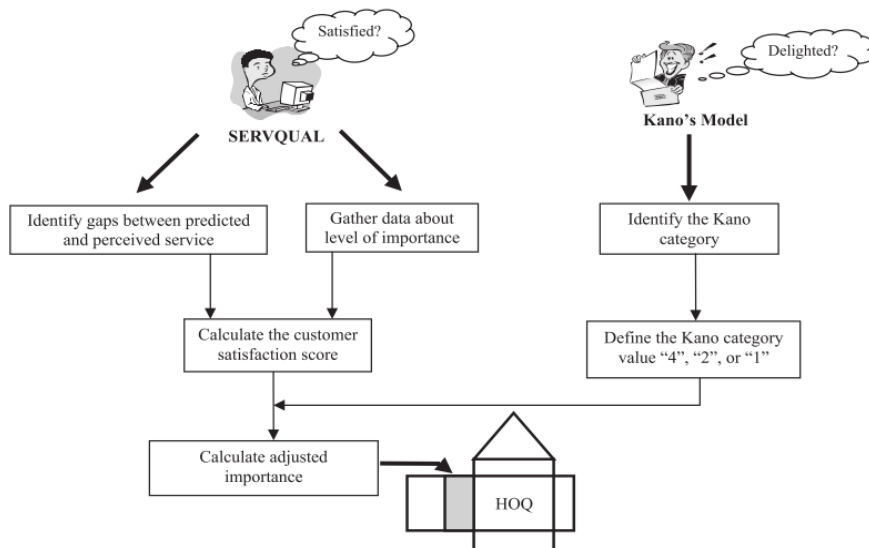

(case of banking service) (Kazemi et al., 2013), application of integrating SERVQUAL and Kano model into QFD (case of logistics service) (Baki et al., 2009), integrating SERVQUAL and Kano model into QFD (case of simulation – based training on project management) (Rahmana et al., 2014), integrating SERVQUAL and Kano model into QFD (case of hotel industry) (P. Gupta & Srivastava, 2012), a hybrid of Kano model and QFD (case of banking service) (Pourhasomi et al., 2013), integrating fuzzy SERVQUAL into refined Kano model (case of restaurant service) (Hsieh et al., 2015), combination of the Kano model and QFD (designing new product) (Tontini, 2007), integrating SERVQUAL and Kano model and QFD (case of PT POS Indonesia) (Singgih & Ardhiyani, 2010) and more. Accordingly, Tan & Pawitra (2001) mentioned and clarified the fundamentals of the procedure involving the collaboration of SERVQUAL, the Kano model, and QFD to evaluate customer satisfaction to develop service excellence and innovation for business organizations. The key arguments or problems for incorporating SERVQUAL and the Kano model into QFD are then briefly reviewed.

**Table 5.** The Major Point for Integrating SERVQUAL and Kano’s Model into QFD

SERVQUAL	Kano’s model	QFD
Assumes a linear relationship between customer satisfaction & service attributes performance.	Helps SERVQUAL to prioritize the improvement of an organization's weakness based on the category of needs that can lead to the highest customer satisfaction.	
As a continuous improvement & innovation tool.	It Helps SERVQUAL to address innovation issues, attractive attributes are a source of customer delight so it is one area where effort for improvement should be targeted.	Generally serves as the planning process for translating customer needs into an appropriate organizational requirement.
Provides important information on the gap between predicate service and perceived service, however, it is not able to address how the gaps can be closed.	Helps SERVQUAL to prioritize which service gap to focus on and to make effort on.	

**Figure 4.** A framework of integrated Kano's model into SERVQUAL.  
Source: Tan & Pawitra (2001)

**Figure 5.** A framework of integrated SERVQUAL and Kano's model into QFD.  
Source: Tan & Pawitra (2001).

Andronikidis et al., (2009) assessed and stated that when working with quantitative methods related to QFD, various issues arise at different stages of QFD execution, as follows: "QFD methodology imposes the need to deal with large amounts of data

gathered from customers, competitors, and cross-functional, time-consuming, requiring input and analyzing a large amount of subjective data, bias may be easily inserted into any stage of the QFD, etc." The employment of quantitative approaches like

the analytic hierarchy process (AHP) is thus necessary to build a new strategy for enhancing QFD's efficacy to resolve those problems. A better service delivery that meets or surpasses client expectations is made possible by the analytic network process (ANP) and Markov chains, increasing sales and customer satisfaction.

### 3. Material and Methods

#### 3.1. Fuzzy SERVQUAL Model

The main steps incorporated in the appraisal of bank service quality are discussed as follows: the questionnaires' design; distributing survey questionnaires and gathering survey data; analyzing customer expectations and perceptions of service quality; and finally, the interpretation of fuzzy SERVQUAL analysis.

#### Step 1. Questionnaire Design

This article adapts questionnaires from previous literature. The SERVQUAL model questionnaires addressing customer perceptions and expectations are weighted

using the linguistic variables scale. For instance, the linguistic variables include "strongly disagree," "disagree," "neutral," "agree," and "strongly agree."

**Table 6.** A linguistic variable of perceptions & expectations.

Likert scale	Linguistic variables	Fuzzy membership function
1	Strongly disagree	(1, 1, 3)
2	Disagree	(1, 3, 5)
3	Neutral	(3, 5, 7)
4	Agree	(5, 7, 9)
5	Strongly agree	(7, 9, 9)

#### Step 2. Distribution of Survey Questionnaires and Collection of Survey Data

A simple random sampling technique was used for the SERVQUAL model questionnaire's respondents. In line with this, the basic formula for calculating the sampling error for a sample estimate of a population parameter is as follows (Bozorgi, 2007).

$$\text{Sample error} = \frac{\text{Variability of the measurement (Values among the sampling units)}}{\sqrt{\text{Size of the sample}}} \quad (2)$$

Also, this article describes a pilot test and the standard variation in factors of service quality measurement in the Grönroos model.

Likewise, table 7 summarizes the standard deviation of service quality variables (Grönroos, 2000).

**Table 7.** Mean standard variation of services quality measurement. Source: Grönroos (2000)

Items	Mean standard variation
Tangibles	0.708
Reliability	0.301
Responsiveness	0.521
Assurance	0.263
Empathy	0.755
Technical factor	0.605
Image	0.603

Therefore, for this purpose, this article considers using a 5% sample error to be adequate for academic research.

Accordingly, to get an accurate sample size, we should select the maximum value of the mean variation of a factor, so the sample size

is calculated as follows:

$$0.05 = \frac{(0.755)}{\sqrt{\text{Size of the sample}}} = 240.24 \approx 240$$

### Step 3. Analysis of Customer Expectations and Perceptions

The main mathematical operations on fuzzy number

Previous literature has discussed the mathematical operations of the fuzzy number (Adamo, 1980; Campos & Verdegay, 1989; Dubois & Prade, 1978; Nahmias, 1978).

The primary mathematical operations on fuzzy numbers include the ones listed below: Triangular fuzzy numbers  $A_1 = (c_1, a_1, b_1)$  and  $A_2 = (c_2, a_2, b_2)$  should be used as examples.

1. The triangular fuzzy number  $Y = (c, a, b)$  is a special case of a generalized trapezoidal fuzzy number. The ranked average integration representation of the triangular fuzzy number  $Y$  will be.

$$P(Y) = \frac{1}{6}(c + 4a + b) \quad (3)$$

2. Addition operation of  $A_1$  and  $A_2$

$$A_1 + A_2 = (c_1 + c_2, a_1 + a_2, b_1 + b_2) \quad (4)$$

Where:  $c_1, c_2, a_1, a_2, b_1, b_2$  are real numbers

3. Subtraction operation of  $A_1$  and  $A_2$

$$A_1 - A_2 = (c_1 - b_2, a_1 - a_2, b_1 - c_2) \quad (5)$$

Where:  $c_1, c_2, a_1, a_2, b_1, b_2$  are real numbers

4. Division operation of  $A$  and any real number  $r$

$$\frac{A}{r} = \left( \frac{c}{r}, \frac{a}{r}, \frac{b}{r} \right) \quad (6)$$

Where:  $r$  are real numbers

5. Multiplication operation

$$P(Y_1 * Y_2) = \frac{1}{6}(c_1 + 4a_1 + b_1) * \frac{1}{6}(c_2 + 4a_2 + b_2) \quad (7)$$

The analysis steps are discussed as follows:

1. Let fuzzy number  $A_{ein}$  be the service quality expectation from the  $n^{\text{th}}$  customer under service item  $i$ , let fuzzy number  $A_{pin}$  be the service quality perceptions from the  $n^{\text{th}}$  customer under service item  $i$ , and let fuzzy number  $TA_{ei}$  be the sum of service quality expectation from all customer under service item  $i$ , let fuzzy service number  $TA_{pi}$  be the sum of service quality perception from all customer under service item  $i$ .

$$TA_{ei} = \sum_1^N A_{ein} \quad (8)$$

$$TA_{pi} = \sum_1^N A_{pin} \quad (9)$$

By using equations (4) & (8) we can analyze the sum of service quality expectations from all customers under service item  $i$ , alike, by using (4) & (9) we can analyze the sum of service quality perception from all customers under service item  $i$ .

2. Let fuzzy number  $MA_{ei}$  be the average service quality expectations from all customers under service item  $i$ , and let fuzzy number  $MA_{pi}$  be the average service quality perceptions from all customers under service item  $i$ .

$$MA_{ei} = \frac{TA_{ei}}{N} \quad (10)$$

$$MA_{pi} = \frac{TA_{pi}}{N} \quad (11)$$

By using equations (6) & (10) we can analyze the average service quality expectation from all customers under service item  $i$ , alike, by using equations (6) & (11) we can analyze the average service quality perception from all customers under service item  $i$ .

3. Let fuzzy number  $Gap_i$  be the gap within the perception and expectation of service quality from all customers under service item  $i$ .

$$Gap_i = MA_{pi} - MA_{ei} \tag{12}$$

By using equations (5) & (12) we can analyze the service quality gap with the expectation and perception from all customers under service item  $i$ , likewise, by using equation (3) we can analyze the representation of a fuzzy number.

### 3.2. Fuzzy Kano's Model

Following is a discussion of the primary methods used to assess the functional and dysfunctional requirements for bank service quality: design, dissemination, and data gathering for Kano model questionnaires; Kano categorization; customer satisfaction and self-stated importance; and, lastly, customer needs and technical requirements.

#### Step 1. Kano's Model Questionnaire Design

This article adapts questionnaires from previous literature. Kano models' functional and dysfunctional interpretations were careful. In line with this, customer responses are weighted using linguistic variables. For example, the linguistic variables include "I like it," "I expect it," "I am neutral," "I can tolerate it," and "I dislike it." And the second type of Kano model questionnaire addresses customers' views on how important a given

feature is to them, and their responses are weighted using the linguistic variables scale. For example, the linguistic variables include "not important," "somewhat important," "important," "very important," and "extremely important."

**Table 8.** Linguistic variables of Kano's model.

Self-stated importance scale	Linguistic variable	Fuzzy membership function
1	Not important	(1, 1, 5)
3	Somewhat important	(1, 5, 7)
5	Important	(5, 7, 11)
7	Very important	(7, 11, 13)
9	Extremely important	(11, 13, 13)

#### Step 2. Distribution of Kano's Model Questionnaires and Collection of Survey Data

The snowball sampling technique was used for Kano's model questionnaire respondents, and the formula for calculating the sample size is as follows:

$$n = \frac{Z^2 * \sigma^2}{e^2} = \frac{Z^2 * P(1-P)}{e^2} \tag{13}$$

$$n = \frac{1.96^2 * 0.3(1-0.3)}{0.05^2} = 322.69 \approx 323$$

#### Step 3. Determine Kano's Classification, Customer Satisfaction Coefficient, and Self-Statement Importance

The customer satisfaction coefficient indicates whether a service's ability to satisfy criteria may boost customer satisfaction or whether doing so only keeps them from being unsatisfied. As seen below, the two equations were used to calculate how satisfied and unsatisfied people were with their lives.

$$\text{Customer satisfaction (better)} = \frac{A + O}{A + O + M + I} \quad (14)$$

$$\text{Customer dissatisfaction (worst)} = -\frac{O + M}{A + O + M + I} \quad (15)$$

#### Step 4. Determine Customer Requirements and Technical Requirement

Utilizing the fuzzy SERVQUAL and fuzzy Kano models, customer needs were determined. A similar concentrated group conversation with the branch manager and customer support representative led to the discovery of the technical necessity.

#### 3.3. Fuzzy Analytic Network Process

The major steps undertaken in the fuzzy analytic network process are discussed as follows.

##### Step 1. Establish Fuzzy Analytic Network Process Pairwise Comparison Matrices

Following the identification of the customer requirement from fuzzy SERVQUAL and

fuzzy Kano model analysis, the next step is to construct a fuzzy pairwise comparison of customer requirements to analyze the weight of each customer requirement, respectively. On the other hand, the analytic network process is weighted using the linguistic variables scale; for instance, the linguistic variables include "equally important," "weakly important," "fairly important," "strongly important," and "absolutely important."

##### Step 2. Analyze The Local Weight of Each Technical Requirement Concerning Customer Requirement

This step entails examining the fuzzy weights associated with each technical requirement and each customer requirement for compliance.

**Table 9.** Linguistic variables of the Analytic Network Process.

Saaty scale	Linguistic variable	Fuzzy membership function
1	Equally important	(1, 1, 1)
3	Weakly important	(2, 3, 4)
5	Fairly important	(4, 5, 6)
7	Strongly important	(6, 7, 8)
9	Absolutely important	(9, 9, 9)

#### 3.4. Integrated Fuzzy SERVQUAL, Fuzzy Kano's Model, and Fuzzy ANP into QFD

The approach incorporated in the design of an integrated HOQ is discussed as follows: Kano categories were allocated based on their fuzzy Kano model analysis, and the importance of "what" was gathered using fuzzy SERVQUAL analysis. The Kano categories were then multiplied with fuzzy SERVQUAL results to determine the

modified importance (importance of "what" value).

Also, the adjusted importance was then multiplied with each technical requirement in the row and summed up the results of the total value to determine the (importance of the "how" value). Briefly, the application of integrated fuzzy SERVQUAL, fuzzy Kano model, and fuzzy ANP into QFD is presented in the figure 7.

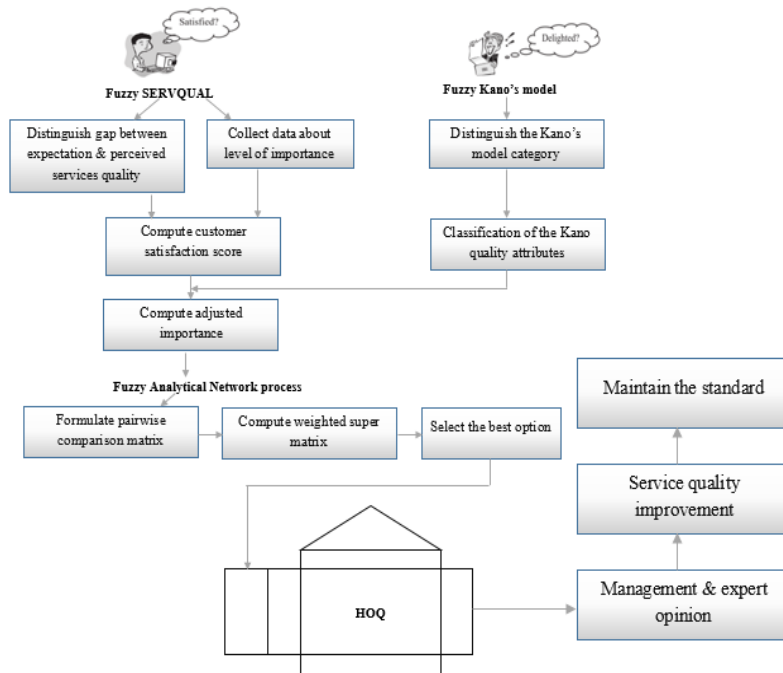

Figure 6. A framework of synergies of fuzzy SERVQUAL, fuzzy Kano's model, and fuzzy analytical network process into QFD.

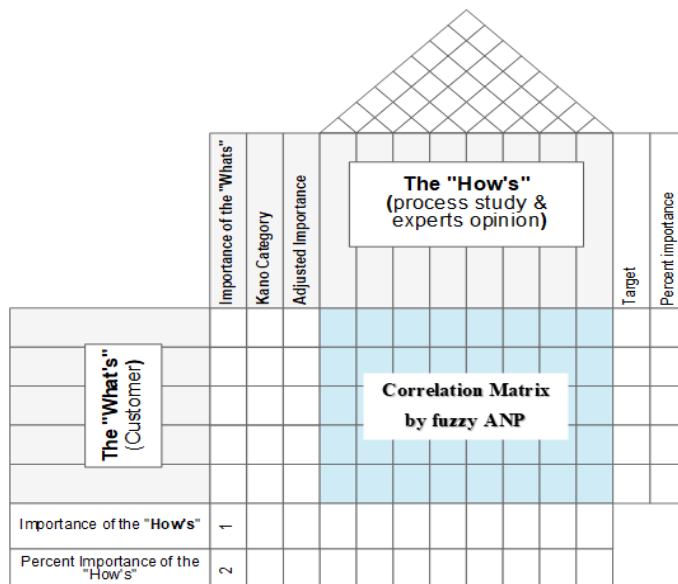

Figure 7. House of Quality (HOQ) for service quality design by using fuzzy ANP for correlation matrix

## 4. Results and Discussion

Based on the statistics obtained from the table below, we can interpret the following analysis result as follows: These include the first variable, reliability, which contains: the bank providing the promised service within a given time frame (-4.478); the bank responding to your claim fast and delivering adequate service within the time frame (-4.324); the bank performing the service right the first time (-3.310); and whenever you face a problem, the bank always shows a sincere interest in solving it (-3.216). The

second variable is responsiveness which contains bank employees delivering prompt service to you (-3.605), bank employees never being too busy to respond to your request (-3.533), and bank employees informing you exactly when service will be performed (-3.491). The third variable is empathy which contains the bank giving care and individual attention to you (-3.219), the bank giving you the best interest at heart (-3.112), and bank employees always understanding your specific needs of you (-3.010).

**Table 10.** The analysis of expectations and perceptions

Dimension	Expectation	Perception	Gap	Rank
<b>Reliability</b>	<b>7.726</b>	<b>4.089</b>	<b>-3.637</b>	<b>-3.637<sup>[1]</sup></b>

Item 22	7.572	4.039	-3.533	-3.533 <sup>[4]</sup>

The majority of client requirements, according to the Kano classification study, are characterized as one-dimensional needs;

thus, the bank should take note of aspects in the design of the service system that suggest greater customer satisfaction. Examples of

one-dimensional items are item 14 (response of 61 and percentage of 60.40), item 3 (response of 57 and 56.44%), and item 1 (response of 53 and 52.48%). This analysis

enables us to determine or identify customer requirements, which also helps the company understand the voice of its customers to improve service quality.

**Table 11.** Kano classification

Customer requirement		A	O	M	I	R	Q	Total	Categories

**Customer Satisfaction Coefficient and Self-Stated Importance**

Based on the statistics obtained from the table above, we can interpret the following analysis result as follows: the self-stated importance analysis indicates that having the promised service within a given time frame (10.845), getting a fast claim response and getting adequate service within the time frame (11.082), having the employee inform

you exactly when the service will be performed (10.796), and having the employee deliver prompt service (10.944) are all significant. This analysis result is critical to distinguish features from each other and helps to know which are most relevant to the customer; therefore, in the next step, we can determine customer requirements from fuzzy SERVQUAL and fuzzy Kano's model analysis results.

**Table 12.** Customer satisfaction coefficient and self-stated importance

Service requirement	$Better = \frac{A + O}{A + O + M + I}$	$Worst = -\frac{O + M}{A + O + M + I}$	Self-stated importance
Item 1	0.68	-0.76	10.845
Item 2	0.38	-0.79	10.093
Item 3	0.80	-0.72	11.082
Item 4	0.47	-0.68	10.231
Item 5	0.68	-0.53	9.212
Item 6	0.60	-0.66	9.954
Item 7	0.56	-0.53	9.895
Item 8	0.47	-0.54	9.548
Item 9	0.48	-0.58	9.845
Item 10	0.44	-0.80	10.092
Item 11	0.63	-0.54	9.806
Item 12	0.78	-0.61	9.726
Item 13	0.53	-0.77	10.796
Item 14	0.62	-0.99	10.944
Item 15	0.67	-0.72	10.944

**Determine Customer Requirements and Technical Requirement**

Customer requirements were identified by using fuzzy SERVQUAL and fuzzy Kano's model. One of the main reasons for

identifying the main customer requirement is to determine which service attributes have a significant effect on customer service perception.

**Table 13.** List of customer requirements

No.	Customer requirement
1	The bank should provide the promised service within a given time frame
2	The bank should respond to customer clam fast and deliver adequate service within the time frame
3	An employee should deliver prompt service to the customer
4	The employee should never be too busy to respond to customer request
5	The employee should inform the customer exactly when service will be performed

Table 14 summarize the main technical requirements based on focused group discussions with the branch manager and

customer support representative led to the discovery of the technical requirements.

**Table 14.** List of technical requirements

No.	Technical requirement
1	Collect customer feedback on a continuous basis
2	Identify dissatisfied customers & frequent service failure issues
3	Update service standards & guidelines
4	Conduct adequate training, performance evaluation & rewards
5	Improve internal service quality by concentrating on employee issues and concerns
6	Establish experience-sharing conducts

**Analyze the Local Weight of each Technical Requirement Concerning Customer Requirement**

Following this, the next step is to determine the fuzzy weight of each customer

requirement correspondingly and evaluate each technological requirement's fuzzy weight by considering customer requirements as a factor.

**Table 15.** Fuzzy weight of customer requirement

	Fuzzy weight				Weight
CR <sub>1</sub>	0.329042	0.397976	0.472305	0.399774	0.4788824
CR <sub>2</sub>	0.078474	0.085344	0.092577	0.085465	0.10237726
CR <sub>3</sub>	0.056147	0.066162	0.078717	0.067009	0.08026851
CR <sub>4</sub>	0.166245	0.213171	0.264957	0.214791	0.25729409
CR <sub>5</sub>	0.051774	0.066162	0.085367	0.067768	0.08117774
	<b>Total</b>				0.834807
					1

**Acquire the Weighted Supermatrix**

In this section, the main task is to construct the weighted supermatrix; having done that,

the next step is to multiply each column of the technical requirement by a fuzzy weight.

**Table 16.** The weighted supermatrix

	Weight	TR <sub>1</sub>	TR <sub>2</sub>	TR <sub>3</sub>	TR <sub>4</sub>	TR <sub>5</sub>	TR <sub>6</sub>
CR <sub>1</sub>	0.479	0.354697	0.068647	0.255945	0.163718	0.125744	0.031248
CR <sub>2</sub>	0.102	0.241429	0.075028	0.097211	0.097211	0.244401	0.100502
CR <sub>3</sub>	0.080	0.270366	0.046822	0.132208	0.273316	0.054156	0.223131
CR <sub>4</sub>	0.257	0.222068	0.050393	0.102766	0.270215	0.114411	0.240147
CR <sub>5</sub>	0.081	0.12392	0.18745	0.121312	0.182614	0.117983	0.266722

**Analyze the Comprehensive Weight**

When the abovementioned stage is complete, we may build the relationship matrix

between customer needs and technical requirements, which is needed for HOQ analysis.

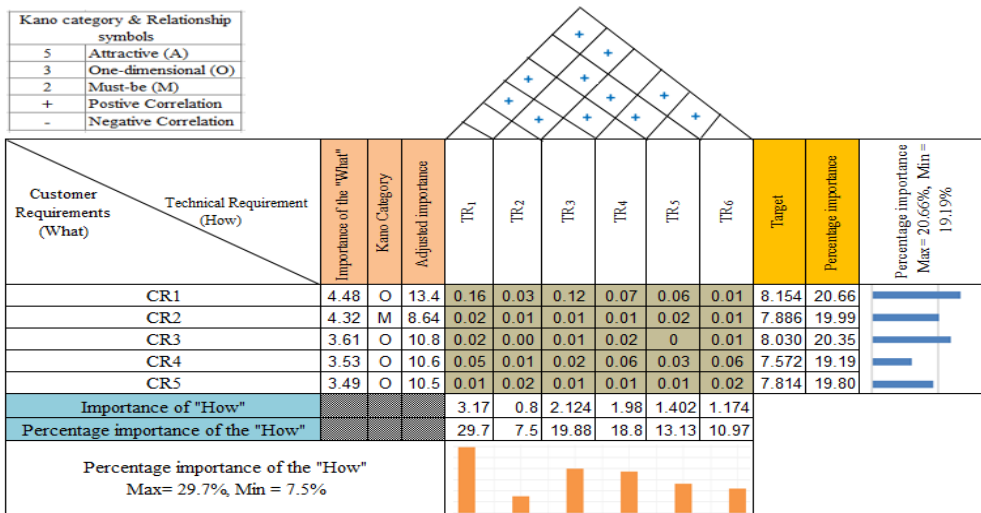

**Table 17.** Relationship matrix between customer requirement and technical requirement

	TR <sub>1</sub>	TR <sub>2</sub>	TR <sub>3</sub>	TR <sub>4</sub>	TR <sub>5</sub>	TR <sub>6</sub>
CR <sub>1</sub>	0.169858	0.0328738	0.122568	0.078402	0.060216	0.014964
CR <sub>2</sub>	0.024717	0.00768115	0.009952	0.009952	0.025021	0.010289
CR <sub>3</sub>	0.021702	0.00375836	0.010612	0.021939	0.004347	0.01791
CR <sub>4</sub>	0.057137	0.0129658	0.026441	0.069525	0.029437	0.061788
CR <sub>5</sub>	0.01006	0.01521673	0.009848	0.014824	0.009578	0.021652

**Integrated Fuzzy SERVQUAL, Fuzzy Kano's Model, and Fuzzy ANP into QFD**

From the integrated HOQ analysis, prioritize the technical requirements based on their importance, for example, collecting customer feedback continuously with a value of 29.7%, updating service standards and guidelines (19.88%), conducting adequate training, performance evaluation, and reward (18.8%), improving internal service quality

by concentrating on employee issues (13.3%), establishing experience sharing practices (10.97%), and finally identifying dissatisfied customers and frequent service failure issues (7.5%). Accordingly, the study claimed that enhancing each of those technical requirements might enhance the bank's level of customer satisfaction through higher service quality.

**Figure 8.** Integrated House of Quality

Besides, the analysis also prioritizes the customer requirements based on their importance. The bank should provide the promised service within a given time frame (20.66%), and an employee should deliver prompt service to the customer (20.35%). The bank should respond to a customer's claim fast and provide adequate service within the time frame (19.99%); the employee should inform the customer exactly when service will be performed (19.80%). And the employee should never be too busy to respond to customer requests (19.19%). Therefore, this article declares that fulfilling those customer requirements can increase customer satisfaction.

## 5. Conclusion

With the increasing progress in bank service in today's competitive market, people experience fast and prudent service delivery of bank service this phenomenon has enhanced customer expectations about bank service. The finding has a practical

implication for service industries to explore their drawbacks related to service quality. Likewise, increase customer satisfaction and increase their competitiveness in the current marketplace. The bank should also constantly collect customer feedback, identify the root causes of service failures that commonly leave customers dissatisfied, update service standards and guidelines, and implement proper training, performance assessments, and incentive schemes. And raise the standards of internal services by emphasizing worker issues and concerns. And finally, establish procedures for exchanging experiences.

**Acknowledgments.** I am grateful to the International Journal for Quality Research Editorial Office and its reviewers for investing the time and effort necessary to evaluate the manuscript. My sincere gratitude goes out to everyone who offered wise comments and suggestions that helped me improve the quality of the manuscript.

## SYSTEM OF BALANCED INDICATORS FOR NEW PRODUCT DEVELOPMENT STRUCTURES TAKING INTO ACCOUNT CUSTOMER SATISFACTION

**Abstract:** *This study considers the usage of balanced scorecard for planning and operative management of organisations responsible for developing new products. It is proposed to use five perspective of strategic map, taking into account the key strategy - development and commercialization of the intellectual activity results. In addition to four standard projections it is suggested to use the Customer Satisfaction projection.*

*This perspective includes the goals of increasing characteristics of the input flow developments coming or being created at the enterprise. It also reflects the quality objectives regarding the products created in the enterprise.*

*For each goal, indicators for monitoring their implementation are defined.*

*This balanced scorecard can be used as a starting point in building a model for evaluating organisational structures, and also develops the theory of planning and management development and production processes.*

**Keywords:** *management, organisation of production, quality, new products, organisational structure.*

### 1. Introduction

For the building an effective system of planning and operational management of the organisation's structures responsible for the development of new products it is necessary to determine the strategic purposes of the development company of additive manufacturing and carry out their decomposition to the level of separate units. It is sufficient to choose only these purposes which can be influenced by the activity of development units. Monitoring the implementation of objectives is carried out through the indication system where every aim is assigned to key performance

indicators.

Nevertheless, the aim of selecting the main points and indicators of their achievement for the organisational structures, working on creation of additive products, becomes non-trivial.

In rates elaboration it is essential to point out that realisation of new products, also in the additive technologies, being implemented within the project activity, which is oriented on meeting requirements of all projects' stakeholders. A balanced scorecard (BSC) is the most used instrument to identify strategic rates and metrics of their implementation. This method is considered to be more versatile from the management point of

view, since such a system of goals can be used in different spheres on various levels of management.

Methodology of setting strategic objectives on the basis of a balanced scorecard has been used for a long time and recognised by many managers as an effective instrument for planning and managing. A traditional scorecard, proposed in 1992 by R. Kaplan and D. Norton, includes four projections: finances, processes, market and people.

Nowadays, it is important to notice that the external environment of the companies, developing additive technologies, becomes dynamic and non-permanent and the rate of technology diffusion is constantly increasing, which leads to a reduction in the life cycle of new product development projects. The focus of project management is shifting from meeting the project objectives and a product delivery to meeting client's requirements and supplying value.

However, in this interpretation, the indicators do not cover areas related to the supplying value to the customer of new products and stakeholders. Usage of unified projections seems insufficient, since it does not reflect the specifics of the activities of individual departments involved in the development of new products, and also does not allow assessing how the delivered results satisfy the customer. After all, in the end, it is this factor that determines the efficiency of the functioning of the entire system. In this regard, the formation of a modified system of balanced indicators of new product development structures, taking into account customer satisfaction, becomes an urgent task.

Many domestic [L.R. Batukova & Belyakova, 2015; E.V. Chmyshenko, & Satenaeva, 2019; V. V. Ermolenko et al., 2021; V.S. Kankhva, 2019; O.A. Kolegova & Zakharova, 2018; A.S. Shevchenko, 2017; N.S. Tsygankov & Petrunina, 2022; A.I. Utkin & Shitik, 2020; A.I. Utkin, Marintsev

& Utkin, 2020; A.I. Utkin & Tikhomirova, 2020] and foreign [V. Bohm, Lacaille, Spencer & Barber, 2021; R.E. Brimelow et al., 2022; T.H. Davenport, 2018; L.E. Farci, 2021; G.F. Frederico, Garza-Reyes, Kumar, & Kumar, 2020; E.G. Hansen & Schaltegger, 2017; E. Pierce, 2022] researchers, considering the application of a balanced scorecard for management structural subdivisions of enterprises note the need to form additional projections that meet the strategic goals and industry specifics of specific enterprises

## 2. Building a strategic map

As a methodological basis for the study, recommendations were used on the formation of a balanced scorecard of the Group of Companies "Modern Management Technologies" [Reference, nd].

In the context of project management for the development of new products in the additive industry, in order to determine new projections of the balanced scorecard, it is advisable to refer to modern project management standards. In the latest edition of the Guide to the Project Management Body of Knowledge [Guide to the PMBOK, 2021] from the leading American project management institute PMI, the fundamental principle is the delivery of value, not the product of the project, since it is this fact that ensures maximum satisfaction of stakeholders, and the customer of new products in the first place. It must be understood that it is customer satisfaction that determines the fulfilment of the goals of the "Market" projection and determines the level of achievement of the company's financial goals, which are the dominant projection in the balanced scorecard.

In this regard, the issues of including customer satisfaction criteria in the balanced scorecard are an important task of strategic management.

Within the framework of this study, in addition to the traditional four projections, it is proposed to introduce another one that reflects the degree of customer satisfaction with new products.

Table 1 reveals the essence of each projection (perspective) in accordance with the main strategy of the enterprise - the development of additive equipment.

For enterprises developing new equipment, it is required to define key indicators for each perspective.

**Table 1.** Essence of projections (prospects) of the balanced scorecard

Perspective	Description
Finances	It reflects the key financial and economic goals of both individual organisational structures for the development of new products, and the entire enterprise. Includes income and expense components
Clients (market)	Includes goals aimed at working with intermediate (within the distribution network) and end users and consumers of services and products, created on the basis of additive technologies
Processes	Reflects the key goals of creating, developing and improving individual processes for developing new products at the enterprise, interaction between all departments of the company
Staff training (Potential)	Includes goals related to the creation and development of internal points of growth, the improvement of the personnel component, as well as the increase in the efficiency of distribution and use of various types of resources or the creation of new ones
Customer Satisfaction	Indicates the goals of increasing the qualitative and quantitative characteristics of the input stream of developments coming and being created at the enterprise. It also reflects the goals of quality and individual parameters regarding the products created at the enterprise in accordance with the stage of development or life cycle

As key financial indicators, we highlight:

- increase in net profit. This indicator is used if the company does not have a significant increase in the scale of activities (an increase in the number of employees, the number of products created, etc.). In this case, the positive dynamics in the company will be associated with a reduction in the required investments, a reduction in R&D costs, or an increase in the effectiveness of the transfer process. Otherwise, the indicator may show negative dynamics and not be the basis of an effective management tool;
- increase in revenue. It is an alternative to increasing net profit if the company constantly increases the range of products through self-development and commercialization.

In order to define metrics from a market perspective, it seems necessary to identify specific customer segments for an additive manufacturing company.

Intermediate and end users of the results of the activities of innovative enterprises involved in the development of additive equipment, as well as their partners, can be called:

- industrial enterprises using additive technologies directly in production processes, tooling, prototyping or on repair lines of their own equipment;
- enterprises engaged in research, development and engineering of products using additive equipment;
- scientific and educational institutions that use additive technologies as part of the educational process (for example, "Tochki Rosta" project);
- distributors and dealers focused on the sale of additive equipment, materials and related products;
- individuals using personal equipment (3D printers, 3D scanners) for personal use or as part of a craft activity.

Based on the analysis of identified stakeholders in the use of additive equipment, a number of goals can be identified for the "market" perspective:

- ensuring the versatility of equipment for additive manufacturing. It is determined by the range of supported materials for manufacturing, the ability to configure 3D printing parameters to solve different types of tasks, the availability of support for various production technologies;
- formation of a perception of the correspondence between the price and quality of additive equipment in terms of their consumer and technical characteristics;
- ensuring a high degree of integration of additive manufacturing software systems with enterprise automated control systems;
- reduced requirements for 3D printers and users of additive process control equipment, regardless of the type of device, the

task being solved, and the industry of application;

- ensuring the availability of all elements of the additive manufacturing ecosystem for the full production cycle, including the manufacture and preparation of material, the creation of 3D models, management software, additive manufacturing, devices for post-processing and testing of finished products;
- formation of a high degree of integration of additive equipment into production chains for the production of final products.

One of the main goals of the "processes" perspective is to create an effective mechanism for the development of new additive equipment of the required quality with the optimal use of enterprise resources. It is the organisation of the activities of individual organisational structures in terms of development quality requirements, the operational management of departments and the distribution of resources between them that can achieve this goal.

Other objectives of this perspective are the key processes of infrastructure functioning:

- Ensuring that the input flow of developments is consistent with the planned one. Depending on the enterprise under consideration and its economic and social characteristics, it is necessary to determine the possible speed of development, the severity of input quality requirements, the number of considered quality indicators of the developed products, etc. However, regardless of these features, the key task is to adjust the parameters of the structures organisations responsible for development, in such a way that the planned qualitative and quantitative

indicators of those entering the development structure are observed;

- increase in the speed of development of new products at the enterprise. At each stage, various activities can be carried out to develop and strengthen the potential of the company's structures, including the development of competencies, the provision of resources. As a result, the company increases the scale of activities, expands the range, or improves the products or services provided;
- increasing the success of ongoing R&D and R&D to create new additive equipment. The main task of the departments of the enterprise responsible for the development of new products is to bring innovation to the final stage of the life cycle. Therefore, it is important to select projects that have a high potential for practical value;
- improving the management system of new product development structures to help achieve the company's key goals set for the short or medium term.
- As for the "potential" projection, based on the activities of the development structures, the following key goals can be distinguished:
- reducing the shortage of resources, primarily financial, required for the development of new products;
- increasing the degree of mutual use of the obtained results of intellectual activity both within one organisational structure and within the entire organisation;
- lack of unused resources. When the development structure is running for a long time, a surplus or completely unused resources may be formed. A typical example is

information resources, but it can also apply to material resources arising in the form of residuals as a result of improper planning.

The "customer satisfaction" perspective is aimed at evaluating and developing projects for the development of new products in the enterprise and includes the following goals:

- qualitative development of the developed additive equipment. Innovative companies should not only strive to increase the range of products or carry out periodic updates, but also ensure that they meet or outstrip the existing world technological level for each type of additive equipment;
- formation of protectable results of intellectual activity on the basis of increasing the research potential. Taking into account the considered approaches to assessing the effectiveness of organisational structures involved in the development of new products, it was found that the possibility of forming titles of protection plays an important role. If the enterprise is engaged in the development of media materials and research in the field of additive technologies, then it is additionally necessary to evaluate them;
- increasing the efficiency of the approaches, methods and models used to develop new products. The key task in this case is to choose the best control actions to ensure the stable development of organisational structures and, as a result, increase the development speed, the maximum number of simultaneously created products, and other indicators characterising the development efficiency;
- ensuring a synergistic effect within the framework of the interaction of individual organisational structures for customer satisfaction in the development of new products. First of all, this can be seen in a comparative analysis of the effectiveness of their functioning, which causes competition between departments and orientation to the

leader. Secondly, it is important to transfer projects for the development of new products between individual organisational structures both as part of the direct development process and in the case of a return for revision with a feedback mechanism;

- reduction of technological gap time (the time between the obsolescence of the current product and the release of a new one). The result of the activity of the process of developing new products is not only its creation and introduction to the market, but also the provision of the required parameters of commercialization and the achievement of the required sales volume;

- reduction of terms of commercialization of innovations. With a decrease in the duration of the life cycle of goods and increasing digitalization, which further accelerates this process, it is required to introduce mechanisms for the rapid introduction of innovation to the market.

To display interrelated goals, we will form a strategic map without specific indicators for monitoring their implementation. As the main financial goal, they chose "increase in revenue". As a result of the analysis of the selected goals, key relationships between them were established.

Most of the indicators of the "Customer Satisfaction" perspective contribute to the achievement of the goals of the "Processes" and "Potential" projections, with the exception of the goal "Reducing the time of commercialization of innovations", which is aimed at increasing the company's revenue as a whole.

It is important to note the impact of all goals of the Process projection on all goals of the Market projection, which is associated with

meeting the needs of intermediate and end users of additive equipment by increasing the efficiency of the development process.

The reverse situation is with the goals of the "Market" projection, which have a general impact on the financial goal of the functioning of both individual organisational structures of development, and the entire enterprise as a whole. The result of the construction of a strategic map by the authors is shown in Figure 1.

The recommended number of indicators for one goal is no more than 2-3. Based on the analysis of indicators for assessing individual infrastructure facilities of the enterprise, we selected and adapted the indicators presented in Table 2.

The indicators obtained make it possible to evaluate the organisational structure involved in the development of new products, in general, taking into account the current strategy - the search, selection, development and commercialization of the results of intellectual activity in the field of additive technologies.

To obtain an integral indicator, depending on the characteristics of the strategy of a particular organisational structure, it is required to determine their significance [N.S. Tsygankov, Kasimova & Moskalev, 2017]. In addition, any organisational structure for stable and long-term development must have the property of homeostasis.

An effective tool for determining the significance of indicators in the presence of statistical data is neural network analysis, which demonstrates qualitative results when working with such complex systems [T.H. Davenport, 2018; A.K. Moskalev, Petrunina, & Tsygankov, 2020; E. Pierce, 2022].

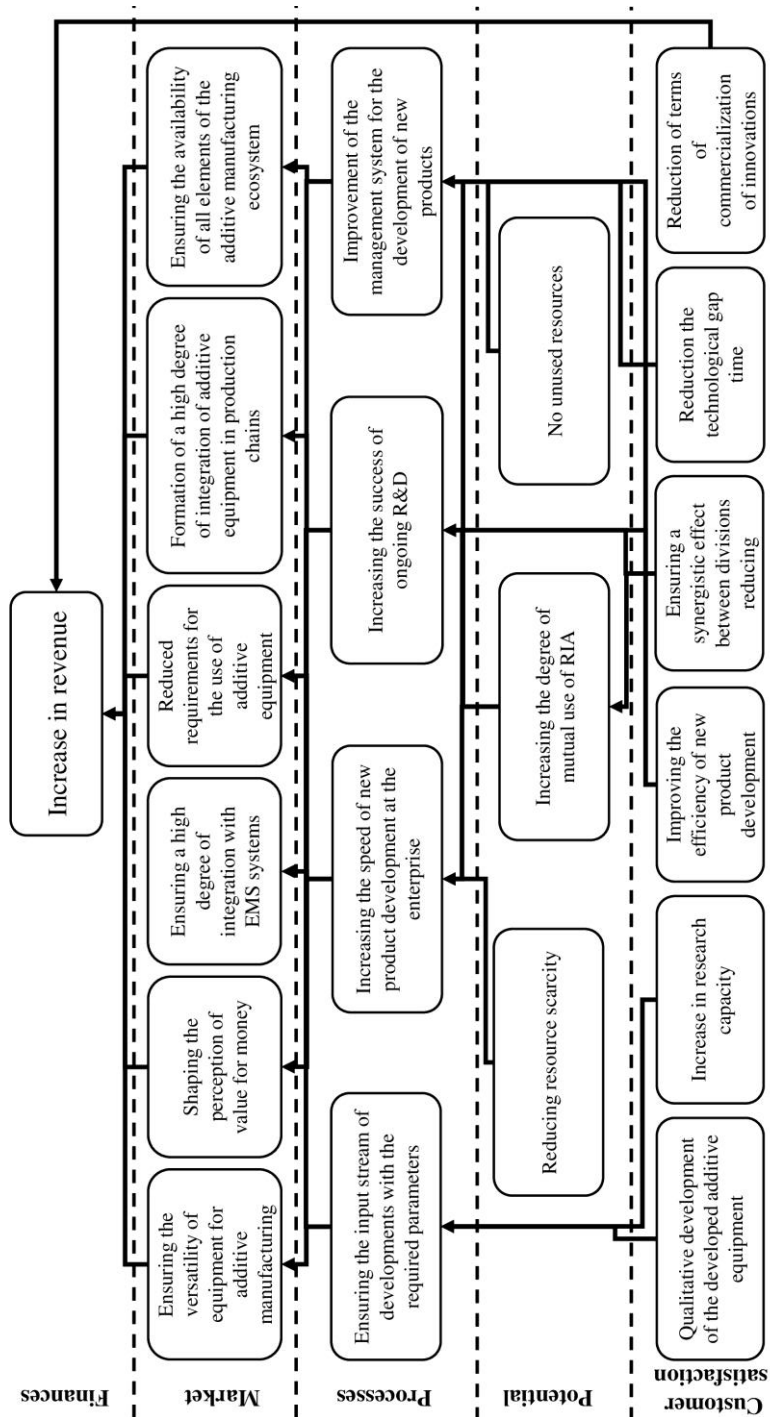

Figure 1. Strategic map

**Table 2.** Indicators of achieving the strategic goals of the organisational structure for the development of additive equipment

Purpose	
1. Increasing revenue	1. The percentage of growth in the total revenue of the enterprise 2. The share of the enterprise's revenue received from the sale of additive equipment developed by the organisational structure (or participating in the development)
2. Ensuring the versatility of equipment for additive manufacturing	1. Number of supported types of additive processes 2. The number of tasks solved by additive equipment 3. Number of materials supported for additive manufacturing
3. Formation of the perception of price / quality compliance	1. Percentage of surveyed buyers who believe that the price of additive equipment is too high (the sample should include both legal entities and individuals) 2. The share of abandonment of the purchase due to the high price 3. Percentage of surveyed buyers who believe that the price of additive equipment is too low (the sample should include both legal entities and individuals)
4. Ensuring a high degree of integration with Enterprise Management Systems(EMS)	1. An indicator of the level of integration. Separate objects of additive equipment and the EMS are selected as subsystems
5. Reducing requirements for the use of additive hardware	1. The number of calls of the consulting type on working with equipment to the technical support of the enterprise 2. Percentage of operations for setting up, launching and maintaining additive equipment that require the participation of an operator (not including the preparation of a 3D model)
6. Formation of a high degree of integration of additive equipment in production chains	1. SRL [O.V. Kalashnikova, Petrunina, Tsygankov & Moskalev, 2019; O.V. Kalashnikova, Petrunina, Tsygankov & Moskalev, 2020]. Separate objects of additive equipment and production technologies are selected as subsystems
7. Ensuring accessibility of all elements of the additive manufacturing ecosystem	1. The percentage of availability of specialised additive manufacturing equipment to ensure the full cycle of additive manufacturing for a particular type of technology (including software for preparing and working with 3D models, managing and controlling 3D printing, producing materials for additive manufacturing, etc.)
8. Ensuring the input stream of developments with the required parameters	1. Number of developments excluded during the initial evaluation (at the idea stage) 2. Average percentage of deviation of parameter values from the required level for excluded developments
9. Increasing the speed of new product development in the enterprise	1. Average time of work on a project to create a new product in the organisational structure, regardless of the result of the work 2. Maximum time to work on 1 new product development project
10. Increasing the success of ongoing R&D	1. Percentage of completed developments relative to those accepted for work by the organisational structure 2. Percentage of completed developments, relative to entering the organisational structure
11. Improving the management system for the development of new products	1. The degree of contribution to the implementation of the company's key goals. Determined by using expert approaches 2. Change in the integral indicator of the effectiveness of the organisational structure

12. Reducing the resource gap	<ol style="list-style-type: none"> <li>1. Number of changes to the work plan of the organisational structure due to lack of resources</li> <li>2. The share of the missing volume of each type of resources relative to the total volume</li> </ol>
13. Increasing the degree of mutual use of results of intellectual activity (RIA)	<ol style="list-style-type: none"> <li>1. Share of intellectual property used at least once in the development of other products</li> <li>2. The number of RIA not used in the developed products</li> </ol>
14. No wasted resources	<ol style="list-style-type: none"> <li>1. Free capacity</li> <li>2. Average equipment downtime</li> <li>3. Share of unused information resources</li> </ol>
15. Qualitative development of the developed additive equipment	<ol style="list-style-type: none"> <li>1. Average increase in the required quality indicators of the developed products relative to the previous development cycle</li> <li>2. The degree of compliance with the world technological level. Determined using an expert approach</li> </ol>
16. Increasing research capacity	<ol style="list-style-type: none"> <li>1. The share of highly qualified personnel in relation to the total number of employees</li> <li>2. The share of received protected RIAs relative to the total number of RIAs</li> <li>3. The number of proposals received for the creation of new products from the employees of the unit</li> </ol>
17. Improving the efficiency of new product development	<ol style="list-style-type: none"> <li>1. Maximum number of development projects implemented by the division</li> <li>2. The number of re-finishing projects for the creation of new products (returns to the previous stage of development)</li> </ol>
18. Ensuring synergies between departments	<ol style="list-style-type: none"> <li>1. Discrepancy between the performance of the worst and most successful organisational structure</li> <li>2. Average time to transfer development between organisational units</li> <li>3. Reduction of development time with the parallel participation of several organisational structures relative to the average development time</li> </ol>
19. Reduction of technological break time	<ol style="list-style-type: none"> <li>1. Duration of the period of decline in sales of a new product from one model range</li> </ol>
20. Decrease in terms of commercialization of innovations	<ol style="list-style-type: none"> <li>1. Average time from receipt of development to the organisation of production and marketing</li> </ol>

### 3. Conclusion

The proposed perspective "Customer Satisfaction" includes the goals of increasing the qualitative and quantitative characteristics of the input stream of developments coming or being created at the enterprise. It also reflects the goals of quality and individual parameters regarding the

products created at the enterprise in accordance with the stage of development or life cycle.

The developed balanced scorecard can be used as a starting point in building a model for evaluating organisational structures, and also develops the theory of planning and managing development and production processes.

## QUALITY EVALUATION OF CONCRETE BLOCK FOR WALLS PRODUCTION USING STATISTICAL PROCESS CONTROL (SPC) TOOLS: A PALESTINIAN CASE STUDY

**Abstract:** *The objective of this article is to assess the feasibility of using statistical process control (SPC) techniques in the concrete block for walls production systems of the Palestinian construction companies to enhance their processes. The study specifically focused on improving the production process of the normal concrete block as it is the most commonly used type in the local market. To achieve this, a local construction company was chosen as a case study to monitor the density, crushing load and compressive strength of concrete blocks using various quality tools such as histogram, control charts and cause-and-effect diagrams. The findings demonstrate that these tools can be effectively implemented in this sector to improve production processes, resulting in material and cost savings.*

**Keywords:** *Statistical Process Control (SPC), Quality, Concrete Block, Variable Control Charts, Construction Materials, Capability Analysis*

### 1. Introduction

Quality is an essential aspect of any product, service, or experience. It refers to the degree of excellence or superiority of something, and it is a critical factor that determines whether something meets or exceeds expectations.

Nowadays, companies should adopt quality management strategies to increase their efficiencies and enhance their competitive advantage (Bottani et al., 2021) due to the influence of globalization as the competition between companies becomes intense and harsh (Manajemen et al., 2020) that led organizations to be more innovative in producing higher quality products with less cost as much as possible to maintain their competitiveness (Matias et al., 2016). So, it becomes mandatory for every organization

to adopt a continuous improvement methodology as an ongoing effort to improve processes (Gejdoš, 2015). The implementation of quality tools and methodologies is necessary to improve processes through reducing process variability, defective items and thus reducing the overall quality cost (Sousa et al., 2017). Statistical Process Control (SPC) is considered as an industrial tool to address a process variation through measuring the process (Keller et al., 2020). This tool is widely used in manufacturing industries to control and manage quality (Chen, 2020). Also, it can easily detect any abnormalities in the product quality in a scientific manner (Zan et al., 2020). Improving product quality and stabilizing production processes requires SPC as a set of problem solving tools (Azarmizad et al., 2022). The use of SPC helps organizations to identify and correct

problems early, before they become serious issues that can affect product quality and customer satisfaction. As well as other constructions materials, concrete block for walls production has no exception in SPC implementation areas as it can be beneficial in improving the quality of blocks, reducing production cost and enhancing customer satisfaction. The concrete blocks have several measures and quality characteristics to be monitored and controlled to ensure their quality consistency and conformance to standards.

One of the main challenges in implementing SPC tools is the lack of expertise and training in statistical analysis and quality control as they are rarely applied in the Palestinian construction materials production market (Haddad, 2021). So that the main aim of this article is to explore how SPC tools can be implemented in such an important product like concrete blocks for walls to meet the Palestinian Standard of PS 6:2010. This article is considering the main quality characteristics which are: density, crushing load, and compressive strength.

## **2. Literature Review**

SPC is a quality management methodology that plays a critical role in monitoring and regulating industrial processes to ensure optimal efficiency and effectiveness. It finds wide-ranging applications in various sectors such as healthcare, manufacturing, and services. SPC is superior to other quality methods such as end product inspection as it enables the identification of faulty machines that could affect product quality. Consequently, operators need to be trained, and new documents need to be created to ensure the optimal performance of machines so that it is recommended to establish a monitoring system to review progress and results, with equal priority to financial outcomes (Madanhire & Mbohwa, 2016). SPC is not just a basic means of detecting

defective production, but it is also an effective method of preventing such production and considered as the most efficient and prevalent tool for managing process variability (Görmen, 2022). To ensure the effective implementation of SPC, several critical factors must be in place. These factors include management's dedication, teamwork, measurement system analysis, process prioritization, pilot project selection, comprehensive training, among other essential ingredients (Antony, 2000). By applying the SPC method objectively, waste can be eliminated, defects can be reduced, and process quality can be improved. However, if the SPC method is subjectively applied, it requires a high level of process commitment as the implementation of the method must be consistently carried out (Isniah & Purba, 2021).

SPC finds widespread applications across several industries, including manufacturing, healthcare, and service sectors. In the manufacturing industry, SPC is a popular tool to enhance product quality by identifying and preventing defects in the production process. SPC enables manufacturers to identify process variations and implement necessary corrective actions to ensure that the product quality is consistent.

The following are literature reviews regarding the most recent implementations of SPC. The quality characteristics of plastic moldings for the automotive industry was assessed using the Shewhart control charts method to evaluate the measured width and length of the plastic moldings produced through statistical analysis. The stability of the process has been confirmed, which demonstrated that the process was well-set. It was important to ensure the correct chronological arrangement and regular acquisition of measured values when setting the control charts (Malindzakova et al., 2023).

A novel method was presented for interpreting process capability indices in the context of assessing the performance of complex health profiles in the human body. Profile monitoring, a widely used multivariate statistical technique, is often too intricate or unfeasible when dealing with such profiles. To address this issue, the proposed method involves converting the health profile into a univariate specification by means of dissimilarity indices. The effectiveness of this new approach was demonstrated through a simulation study that employs human blood pressure profiles as an example (Nemati & Mehrdoost, 2023).

Faults in wind turbines and predict maintenance needs of wind turbines in Taiwan was diagnosed through employing statistical process control and machine learning techniques. Unlike previous studies that relied solely on historical wind turbine data, this study also integrated maintenance check list items into the data mining process, thereby incorporating practitioners' insight. Various methods such as Pareto analyses, scatter plots, and the cause-and-effect diagram were utilized to cluster and classify the different failure types of wind turbines based on the sensor data. Control charts were also used to establish a monitoring mechanism that could detect wind turbine abnormalities by tracking whether operation data deviated from the controls (i.e., standard deviations). Overall, this study provided a comprehensive approach to wind turbine fault diagnosis and maintenance prediction, which could have significant implications for the renewable energy industry (Hsu et al., 2020). Even in today's trend of big data, it is often necessary to monitor the underlying sequential process to ensure its stability and track any changes in distribution over time. SPC charts are a widely used statistical tool for monitoring such sequential processes. Traditionally, SPC charts have been used

mainly in the manufacturing industry for monitoring production lines. However, recent research has introduced new and versatile SPC methods that can extend the application of SPC charts to many big data applications beyond production line monitoring. As a result, it is believed that SPC charts can be a valuable tool for monitoring and analyzing sequential processes in a wide range of applications (Qiu, 2020).

Six Sigma tools were applied to identify and address improvement opportunities in a concrete block manufacturing company. The DMAIC (Define, Measure, Analyze, Improve, and Control) was used to identify problems, performance variables, and results. It demonstrated the effectiveness of Six Sigma in improving production operations, leading to benefits such as reduced machine downtime, decreased scrap, and improved plant layout and production facilities to increase productivity (Morales et al., 2016).

Quality control is essential in the production of construction materials to ensure they meet desired specifications and standards. It is crucial for safety, durability, cost-effectiveness, reputation, and compliance with regulations and codes. Substandard materials can lead to structural failures, injury, or loss of life, and may have shorter lifespans, resulting in costly repairs or replacements. Quality control can save costs in the long run, establish customer loyalty, and prevent legal and financial consequences for non-compliance.

Several articles on the quality of construction material production have been published especially about the quality of ready-mixed concrete (RMC) production systems. The concrete production processes and pouring methods were improved by identifying and evaluating opportunities for improvement. The results indicated that management should adopt systematic

procedures, including the use of quality tools such as histograms, control charts, and fishbone diagrams, to analyze concrete strength data and detect any abnormal variations (Aichouni et al., 2017). Lean Six Sigma has been adopted in the construction industry for the aim to test the hypothesis that Six Sigma can be applied to construction-based production systems using lean construction techniques. The case study involved applying Lean Six Sigma to a concrete-panel production system in a multi-housing complex project, resulting in improved and stabilized production rates. The variation of panel production was used as a critical total quality (CTQ) to measure the performance indicator of the Six Sigma system (Kim & Heon Han, 2012). A review of the basic concepts of process improvement and the benefits of applying these concepts in the construction industry have been reviewed that focuses on the use of basic quality tools to improve the production process of RMC, and presents a case study of a local RMC producer in Hail, Saudi Arabia. The study monitored and analyzed the 28-day compressive strength of the plant using histogram and Xbar-R control charts techniques, and concluded that producers can effectively improve their production processes, save money, and make their processes sustainable (M. Aichouni, 2014). The application of SPC tools has been reviewed in the concrete production systems of Palestinian construction companies, with a focus on improving the production process of B30 concrete. A case study of a local company is used to monitor the compressive strength of their B30 concrete using various quality tools. The analysis indicates that SPC tools can be effectively applied in this sector to improve production processes, save materials, and reduce costs (Haddad, 2021).

### 3. Methodology

The methodology adopted in this work can be summarized as follows:

1. Identifying the process and selecting the critical quality characteristics to be monitored.
2. Determining the method and frequency of data collection.
3. Establishing control charting methodology and setting control limits.
4. Monitoring the process and collecting data.
5. Analyzing the data to determine whether the process is in or out of control.
6. Assessing the process capability.
7. Sugesting corrective actions and improvement proposals if necessary.

### 4. Concrete Blocks for Walls Production

This article considers the most common type of concrete blocks used in the Palestinian Market which is called the normal block as shown in Figure 1.

**Figure 1.** The Normal Concrete Block

The common production steps for concrete blocks used for walls include:

1. **Mixing the ingredients:** Cement, sand, water, and aggregates such as crushed stone or gravel are mixed together in a concrete mixer to create the concrete mixture.
2. **Molding the blocks:** The concrete mixture is poured into molds. The molds are then vibrated to remove any air pockets and ensure the concrete is evenly distributed.
3. **Curing the blocks:** The molds are left to sit for a period of time, typically 24 to 48 hours, to allow the concrete to cure and harden.
4. **Stripping the molds:** Once the blocks have cured, they are removed from the molds.
5. **Finishing the blocks:** The blocks may be trimmed or shaped to meet

specific design requirements, or they may be left with a rough, textured finish.

6. **Storing the blocks:** The finished blocks are stored in a covered area to protect them from the elements until they are ready to be used in construction. These Steps are shown in Figure 2.

### 5.1. The Density Test

The density of the block, which has been dried in the air in a laboratory for at least 3 days, is examined as follows: the block is weighed accurately to 50 grams. Then, the volume of the brick is calculated by multiplying the dimensions of length, width and height. Finally, the density is calculated by dividing the mass of the brick (in kilograms) by its volume (in cubic meters).

**Figure 2.** Concrete Block Production Steps

## 5. Data Analysis and Results

According to the Palestinian Standard, one sample of blocks is defined as a group of three blocks of the same type, size, and shape, produced by a single manufacturer. The sample is randomly selected to represent a single lot of blocks. The results are considering the main three critical quality characteristics: block density, crushing load, and compressive strength. To ensure high-quality concrete block production, several factors must be considered. These include the quality and consistency of the raw materials used, the mix design and ratio of the raw materials, the type and quality of production equipment, and the curing

conditions such as temperature, humidity, and curing time. Proper attention to these factors can impact the strength, density, and durability of the final product.

Twenty-three samples of size three were taken as a preliminary step to construct the appropriate control charts. The results and analysis of each quality characteristics will be discussed in the following sub-sections.

The results are shown in Table 1.

Histogram is used in statistical analysis to identify the underlying distribution of a density test dataset as shown in Figure 3.

**Table 1.** Density Test Results

Sample No.	Density (Kg/m <sup>3</sup> )		
	Block 1	Block 2	Block 3
1	1196	1191	1172
2	1281	1193	1222
3	1298	1257	1176
4	1166	1325	1161
5	1333	1191	1291
6	1220	1243	1164
7	1235	1186	1214
8	1223	1181	1279
9	1317	1292	1292
10	1265	1239	1224
11	1168	1286	1212
12	1322	1297	1197
13	1258	1256	1243
14	1323	1252	1314
15	1261	1242	1274
16	1267	1245	1236
17	1247	1267	1333
18	1284	1288	1331
19	1281	1285	1287
20	1246	1314	1243
21	1249	1218	1276
22	1269	1361	1311
23	1288	1259	1287

**Figure 3.** The Block Density Histogram

Based on the shape of the histogram, it appears that the distribution of block density is roughly normal. However, to confirm this assumption and further validate the normality of the distribution, a normal probability plot was created and tested using the Anderson-Darling (AD) test at a significance level of 0.05. The results of the AD test are displayed in Figure 4. By

conducting this test, the normality of the distribution of block density can be more confidently assessed.

The (AD) test yielded a small AD value of 0.458, indicating that the normality assumption of the distribution of density is reasonable. Additionally, the p-value of 0.257 was obtained from the AD test, which is greater than the significance level of 0.05. Therefore, we fail to reject the null hypothesis that the distribution of density is normal.

**Figure 4.** The Block Density Normal Probability Plot

Then, Xbar-R charts were constructed to ensure the stability of the process before assessing the process capability as shown in Figure 5.

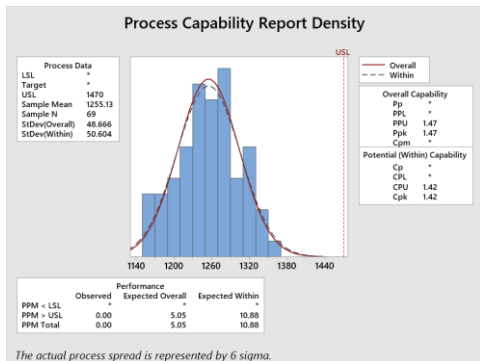

**Figure 5.** Xbar-R charts for Block Density

Based on the control charts, the process was found to be in statistical control and stable. This means that there were no unusual

patterns or outliers detected that would indicate a problem with the process. As a result, no assignable causes were identified that would affect the quality level of the process. The stability of a process in statistical control is crucial for interpreting process capability ratios (PCRs), which are used to assess the ability of a process to meet density specifications.

According to the standard, the maximum nominal value of density is 1400 Kg/cm<sup>3</sup> with no more than 5% above it (i.e., 1470 Kg/cm<sup>3</sup>). To assess the process capability, the resulting estimator of one-sided upper process capability ratio  $C_{pu}$  was calculated to be 1.42 which means that the process is capable of producing output that meets the specifications with a high degree of confidence. These results are shown in Figure 6.

**Figure 6.** The Block Density Capability Analysis

### 5.2. The Crushing Load Test

This load refers to the minimum compressive load or force required to cause a concrete block to fail or break. This load is expressed in in (Kg) according to the standard. The results are shown in Table 2.

**Table 2.** Crushing Load Results

Sample No.	Crushing Load (Kg)		
	Block 1	Block 2	Block 3
1	436	468	391
2	566	448	448
3	535	395	376
4	383	470	220
5	530	306	387
6	473	349	345
7	584	391	398
8	410	379	505
9	566	361	420
10	618	350	385
11	330	494	484
12	569	519	375
13	608	329	496
14	547	555	555
15	552	338	445
16	508	440	332
17	491	439	694
18	525	408	540
19	317	557	462
20	352	430	470
21	515	324	413
22	464	474	576
23	659	429	530

Histogram of crushing load dataset is shown in Figure 7.

**Figure 7.** The Histogram of Crushing Load

Based on the shape of the histogram, it appears that the distribution of the crushing load is roughly normal. A normal probability plot was created and tested using the (AD) test at a significance level of 0.05 as shown in Figure 8.

Figure 8. The Crushing Load Normal Probability Plot

The (AD) test yielded a small AD value of 0.297, indicating that the normality assumption of the distribution of density is reasonable. Additionally, the p-value of 0.580 was obtained from the AD test, which is greater than the significance level of 0.05. Therefore, we fail to reject the null hypothesis that the distribution of density is normal.

Then, Xbar-R charts were constructed to ensure the stability of the process as shown in Figure 9.

Figure 9. Xbar-R charts for The Crushing Load

The process was determined to be in statistical control and stable. This indicates that there were no unusual patterns or outliers detected that could suggest issues with the process. Therefore, no assignable causes were identified that could affect the quality of the process.

According to the standard, the minimum value of crushing load is 300 Kg. To assess the process capability, the resulting estimator of one-sided lower process capability ratio  $C_{pl}$  was calculated to be 0.55 which means that the process is incapable of producing output that meets the specifications and the results are shown in Figure 10.

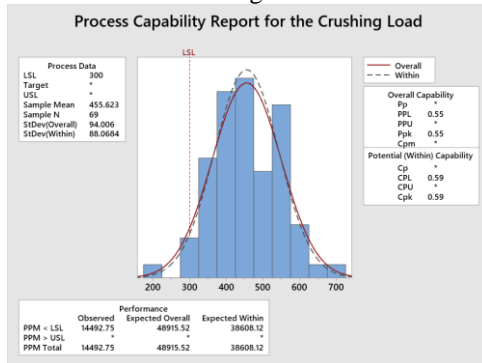

Figure 10. The Block Crushing Load Capability Analysis

The low value of the  $C_{pl}$  was caused by a high level of process variability that negatively impacted the process's ability to meet the required specifications. The underlying reason for this high variability could be traced back to changes in factors such as raw materials, equipment, improper process maintenance and control. These changes likely introduced variation into the process, leading to inconsistent results.

### 5.3. The Compressive Strength Test

The compressive strength of each block is calculated by dividing the crushing load in (N) by the area of the compression surface (in square millimeters). The average compressive strength for the sample is the arithmetic mean of the compression force for the three blocks in the sample. The results are shown in Table 3.

**Table 3. Compressive Strength Results**

Sample No.	Compressive Strength (N/mm <sup>2</sup> )		
	Block 1	Block 2	Block 3
1	5.4	5.7	4.87
2	7.0	5.56	5.49
3	6.72	4.78	4.56
4	4.75	5.86	2.66
5	6.59	3.78	4.8
6	5.94	4.37	4.19
7	7.21	4.78	4.94
8	5.07	4.58	6.27
9	7.06	4.43	5.27
10	7.82	4.36	4.74
11	4.07	6.44	5.9
12	7.01	6.42	4.66
13	7.31	4.08	6.09
14	6.84	6.92	6.89
15	6.78	4.25	5.41
16	6.3	5.42	4.08
17	6.02	5.42	8.57
18	6.56	5.02	6.75
19	4.03	6.95	5.7
20	4.31	5.35	5.85
21	6.3	4.01	5.11
22	5.67	5.85	7.18
23	8.04	5.24	6.59

Histogram of crushing load dataset is shown in Figure 11.

**Figure 11. Histogram of Compressive Strength**

Based on the shape of the histogram, it appears that the distribution of the crushing load is roughly normal. A normal probability plot was created and tested using the (AD) test at a significance level of 0.05 as shown

in Figure 12.

**Figure 12. The Compressive Strength Normal Probability Plot**

The (AD) test yielded a small AD value of 0.401, indicating that the normality assumption of the distribution of density is reasonable. Additionally, the p-value of 0.352 was obtained from the AD test, which is greater than the significance level of 0.05. Therefore, we fail to reject the null hypothesis that the distribution of density is normal. Then, Xbar-R charts were constructed to ensure the stability of the process as shown in Figure 13.

**Figure 13. Xbar-R charts for The Compressive Strength**

The process was also determined to be in statistical control and stable. According to the standard, the minimum value of the compressive strength is 3.5 N/mm<sup>2</sup>. To assess the process capability, the resulting estimator of one-sided lower process

capability ratio  $C_{pl}$  was calculated to be 0.65 which means that the process is incapable of producing output that meets the specifications and the results are shown in Figure 14.

**Figure 14.** The Block Compressive Strength Capability Analysis

The low value of the  $C_{pl}$  was caused by a high level of process variability that negatively impacted the process's ability to meet the required specifications. Since the compressive strength calculation is based on the crushing load, then the underlying reasons for this high variability are the same we mentioned in the previous sub-section. To explore the main causes of this large variation, a fishbone diagram or Ishikawa diagram is adopted to identify the different factors that influence the quality of concrete block production as shown in Figure 15. This diagram aids in exploring the underlying causes of issues and discovering potential solutions. By utilizing this diagram, producers can pinpoint the reasons behind substandard blocks and implement appropriate measures to address them. This may involve enhancing material quality, maintaining equipment, providing worker training, or refining the production process to ensure consistent and high-quality blocks.

**Figure 15.** Cause-and-Effect Diagram

The company was using excess ingredients in the production of concrete blocks to ensure a high crushing load and compressive strength, but this led to increased process variability and waste. Control charts showed that the company was prioritizing high overall averages over consistent adherence to specifications for each batch. The implementation tools can help the company produce high-quality batches with optimal ingredient quantities while reducing variability and cost. The company's current practices lack a clearly documented and planned implementation of SPC tools for continuous improvement and customer satisfaction.

## 6. Conclusions

The objective of this study is to demonstrate how Palestinian concrete block manufacturers can enhance their processes and save money and resources by implementing SPC tools and the results of the case study can be applied to other companies with varying practices. By monitoring the density, crushing load and compressive strength of the normal concrete block and making necessary improvements to their processes, manufacturers can optimize their mixtures and ingredients, ultimately reducing unnecessary material costs. By utilizing these tools, companies can identify the stability and capability of

their production processes, as a first step towards implementing continuous improvement strategies and addressing quality issues. These tools also increase productivity, prevent defects, and reduce the need for unnecessary adjustments. The study suggests that the manufacturers should establish a comprehensive system of documentation, data selection and analysis, training programs, and management

commitment to integrate quality tools into their quality management systems.

**Acknowledgment:** I would like to express my gratitude to the local Palestinian construction company for their valuable assistance in providing us with the required data, which enabled us to successfully complete this project.

## **THE LOW-QUALITY INFLUENCE OF PURCHASING: THE CASE OF FASHION STORES IN INDONESIA**

**Abstract:** *Unplanned purchasing involves buying goods or services influenced by the external environment, creating low-quality purchasing. This research was conducted towards consumers of the Muslim clothing store in Jember East Java, Indonesia, as the population. Accidentally sampling was used to draw 125 respondents to address the questionnaire. The result shows that hedonic shopping, fashion involvement, and store environment influence low purchasing quality in Muslim fashion stores. Most consumers were mature female consumers and government officials with bachelor's degrees. Moreover, hedonic shopping, fashion involvement and store environment significantly influence low-quality purchase decisions. The research implied that consumers' shopping behaviour would underline the quality of buying decisions.*

**Keywords:** *Consumer Behaviour, Low Quality of Purchasing, Hedonic Shopping, Semantic Different*

### **1. Introduction**

The development of increasingly modern retailing has made the business more innovative and has led to the emergence of various business ventures. Along with the varied needs of consumers, it provides opportunities for businesspeople, especially in the fashion sector. According to State Global Islamic Economy, the consumption of Muslim fashion in Indonesia reached US\$20 million with 18.2% yearly growth (Dinar Standard, 2019). This sector contributes 18.1% or IDR 116 trillion to the national economy (CNBC-Indonesia, 2019). This fact has led to many specific retail stores that sell various types of fashion products, both men and women, where these shops provide service facilities and product quality, following the needs and expectations of different consumers

(Sudaryanto et al., 2019; Sudaryanto Sudaryanto et al., 2020).

A Muslim fashion store makes it easy for a specific ethnic of consumers to make purchases. The types of consumers purchasing a product are either rational or irrational (Schiffman & Joseph L., 2015). This rational purchase is planned (Sudaryanto Sudaryanto et al., 2020, 2021). This is an irrational, unplanned, or impulsive purchase (Iram, 2017). Most female consumers are likelier to purchase impulsively (Kwek et al., 2013; Ling et al., 2010). Most impulse buying is fashion shopping (Vinish et al., 2020). The decision with insufficient information and review availability is low-decision making (Elliot, 2018). In a philosophical approach, quality is the experience with universal acknowledgement that the entity has an absolute advantage (D. Garvin, 2007; D. A.

---

Corresponding author: Sudaryanto Sudaryanto  
Email: [sudaryanto@unej.ac.id](mailto:sudaryanto@unej.ac.id)

Garvin, 1987). Accordingly, unplanned purchasing or impulse buying in this study was determined as low-quality purchasing.

Discussing about the shopping behavior, frequently consumer looking at many shops or boutiques that sell various kinds of clothing with various brands, models and, of course, at quite various prices. Jember is one of the cities whose fashion development is starting to rise. This can be seen from the number of Muslim fashion centres in Jember. The collection store here for the wider community, providing various kinds of Muslim clothing collections for men and women for adult, teenager or children sizes. This can indicate that the people of Jember always follow trendy fashion trends, including Muslim consumers. This can certainly trigger impulsive purchases for Jember people who have hedonistic traits or habits. Impulsive buyers usually pay more attention to their appearance and use more items, especially clothing.

Apart from that, the store also provides shoes, sandals, and Hajj and Umrah equipment. For consumers to be interested and motivated to make impulsive purchases, Rien Collection strives to create a comfortable and clean shop atmosphere. although the store sells various kinds of clothing in large quantities and complete, they always arrange the clothes neatly and in order. Other Muslim clothes in the store are mukenah, prayer mats, sarongs and other worship equipment. The products appear nicely in the glass that can be seen by everyone who pass the store and has impulse to buy and experienced in dissatisfaction and will not add a new value inherent. The research problem is then goes to what factors that influences of the low-quality decision purchasing in fashion store with the hedonic shopping, fashion involvement and the store environment.

## 2. Literature Review

### 2.1. The Low Quality of Purchasing

Customer decision making has been studied extensively. the basic assumption underlying this body of knowledge is that customer choices can be explained from a rational perspective where a choice is made after carefully considering different options from a set of alternatives. In some cases, customers violate these requirements of rationality, in such instances, choices are made without careful consideration of the available alternatives, with insufficient information about the product of interest, or without prior intent of purchase on such instance is impulse (Ayu Agustina Pratiwia, 2019; Hasim et al., 2020; Luo et al., 2021; Saad & Madiha Metawie, 2015).

Impulse buying in fashion store categorize as a low-quality decision of purchasing due to unplanned action (Elliot, 2018) (Iram, 2017; Vinish et al., 2020). (D. Garvin, 2007; Ton, 2002) (2007); D. A. Garvin, (1987) identify eight dimension of quality: Performance, Features, Reliability, Conformance, Durability, Serviceability, Aesthetics and Perceived quality (Hoe & Mansori, 2018). The affective response of decision to buy occurs when a consumer sees a certain product or brand and then the consumer becomes interested in getting it, usually because of an attractive stimulus from the store (Peter & Olson, 2010; Schiffman & Joseph L., 2015). This Impulse buying behaviour is often carried out by consumers when shopping, the action taken by consumers is to come and then begin by looking at the product first and deciding which product to buy. The product in question is in the form of a product that was previously planned by consumers for products that consumers did not think about at all. Usually, consumers have a strong urge from their hearts to buy a product immediately without strong self-control.

Hasim et al., (2020; Mirabi,( 2015); and Peter & Olson, (2010) states, unplanned purchases are all purchases made without prior planning, including of purchasing behavior where impulsive buying is making a decision to buy a product that is relatively fast and has the desire to have it immediately.

According to the findings of Li, Deng, and Moutinho (2015), consumers' interest in experience would considerably influence impulsive buying. However, surprisingly, up to the present, when studying marketing activities that encourage consumers' buying, most marketing management researchers neglect consumers' potential impulsive motivation and decision-making factors, as caused by interaction among products, situations, and experience.

The low-quality of fashion purchasing is mostly based on the consumer's affective response. Characteristic features The first consumer affective response is the affective system in general reactive. It means that the affective system cannot plan, make a decision, or deliberately achieve some goal. Even system affective in person usually it responds quickly and automatically toward aspects of significant environment(Burke & Ng, 2006; Hellier et al., 2003; Knoll & Matthes, 2017; Maros & Juniar, 2023; Schimmelpfennig & Hunt, 2020; Simon, 2016; Yuniarto, 2018; Zeithaml et al., 2018)

## 2.2. Hedonic Shopping

According to Chaudhuri, (2000); Kim et al., (2012); and Parsad et al., (2021), hedonic shopping is a motivation based on subjective or emotional thinking, sensory pleasures, dreams and aesthetic considerations. Hedonic shopping becomes a person's psychological needs such as satisfaction, prestige, emotions and other subjective feelings; these needs often arise to meet social and aesthetic demands. Consumers do shopping because they are driven by hedonic

desires or economic reasons, such as pleasure, fantasy and social or emotional satisfaction (Parsad et al., 2021). Since the goal of the shopping experience is to meet hedonic needs, this purchased product looks like it was chosen without planning and will present an Low quality of purchasing process. Hedonic shopping motives are similar to the task orientation of utilitarian shopping motives, only the task is concerned with hedonic fulfillment, such as experiencing fun, amusement, fantasy and sensory stimulation (Kim et al., 2012).

The first proposed hypothesis is:

**H1: hedonic shopping influences significantly towards low quality of purchasing**

## 2.3. Fashion Involvement

Bayley, et al (1998) in Hatane (2007), it is estimated that 65% of purchasing decisions at shopping centres with more than 50% being previously unplanned purchases or low quality of purchasing; this shows that impulsive purchases made by consumers are involved. contribute to the increase in sales turnover obtained by a retail store. Usually, consumers have a strong urge from their hearts to buy a product immediately without strong self-control. According to research by Bayley, et al (1998) in Hatane (2007), it is estimated that 65% of purchasing decisions at shopping centres with more than 50% being previously unplanned purchases or low quality of purchasing; this shows that impulsive purchases made by consumers are involved. contribute to the increase in sales turnover obtained by a retail store.

The development of the fashion world called fashion has experienced rapid progress in Indonesia. Psychologically, fashion is an expression and a person's attractiveness to his social environment. In today's world Fashion has become a common thing and has become everyone's lifestyle. From This lifestyle is the development of fashion

among the people to be a factor which can affect the style or style of each person. People will tend follow current fashion trends. Fashion itself comes from English which means fashion, style, way, model, and habit. In fact the meaning of fashion is different for everyone. The existence of a fashion store makes it easy for consumers to make purchases. The types of consumers purchasing a product are either rational or irrational (Schiffman & Joseph L., 2015).

According to Vinish et al., (2020) fashion involvement is a person's involvement with a fashion product because of their needs, interests, interests and values; fashion can confirm a person's identity in their social environment. Dhurup (2014) suggests that the pattern of impulsive buying behaviour by consumers can refer to the lifestyle of consumers who always follow the development of the fashion trends offered; this can be seen from the attitude and lifestyle of consumers in choosing fashion products, because of the nature of fashion involvement. towards fashion in consumers. Fashion involvement refers to the extent to which an individual finds a number of modes related to concepts, awareness, knowledge, interests, and reactions. To support fashion involvement in the consumer, Muslim Fashion store Jember always strives to provide clothes with trendy designs and the best quality so that consumers will want to buy these products to support their lifestyle. Muslim Fashion store Jember provides a variety of fashion and is always updated so that consumers who see this new product will like it and want to buy it even though it was not planned beforehand.

The second proposed hypothesis is:

**H2: fashion involvement influences significantly towards low quality of purchasing.**

## 2.4. Store Environment

Hussain & Ali, (2015) defines the store environment is a physical store building composed of several elements such as music, lighting, shop form, instructions that direct visitors and human resource elements such as cashiers. The Purpose of the Store Atmosphere that managers need to pay attention to include: Design Must Match Impressions and Strategies, Design Should Influence Positive Consumer Behavior, Design Should Consider Cost and Value, Design Should Be Flexible. Store environment which consists of music, lighting, layout and employees significant effect towards low quality of purchasing (Hasim et al., 2020; Hussain & Ali, 2015; Saad & Madiha Metawie, 2015)

The third proposed hypothesis is:

**H3: store environment influences significantly towards low quality of purchasing.**

## 3. Research Methods

### 3.1. Research Design

The research design used in a study depends on the method to be used in a study and/or the hypothesis to be tested and the variables to be observed. The research design is a master plan that contains methods and procedures for collecting and analyzing the required information (Babbie, 2001; Malhotra & Birks, 2007; Sudaryanto et al., 2021) This research is included in the category of explanatory research that explains the interdependency between predictors and predicted the variables.

### 3.2. Population and Sample

The population in this study were all consumers of the Rien Collection Jember Clothing. The sampling method in this study uses accidental sampling techniques. A non-

probability sampling is a sampling technique that does not provide equal opportunities or opportunities for each element or member of the population to be selected as samples, then accidental sampling is part of non-probability sampling where the sampling technique is based on chance (Malhotra & Birks, 2007). The sample in this study was 125 store consumers of the Rien Collection Muslim store in Jember District, East Java Indonesia, who met the research criteria based on chance.

### 3.3. Data

The primary data was collected from the questionnaire that was distributed to respondents offline before the Ramadhan festival. The response was measured using a Semantic different scale from 1 (very negative to 10 very positive). The data in this research is cross-section data, which was collected in June 2021. According to Sugiyono (2010: 137), primary data is data obtained directly from the original source, in this study related to perceptions of hedonic shopping, fashion involvement, and store environment on low quality of purchasing.

### 3.4. Statistical analysis

Multiple linear regression analysis is used to analyze the data with independent variables Hedonic Shopping (HS) and fashion involvement (FI) and the Store Environment (SE) with Low quality of purchasing (IB) as a dependent variable. Given that this study uses 3 independent variables, the regression equation according to Sugiyono (2010: 277) is as follows:

$$Y = \alpha + \beta_1 IB + \beta_2 HS + \beta_3 FI + \epsilon$$

### 3.5. Classic assumption test

The Gauss-Markov theorem consists of six classical assumptions that must be met when conducting multiple linear regression

analysis or ordinary least squares (OLS). This is well-known as BLUE (Beest Linear Unbiased Estimator), considering that not all data can be applied to regression and represent the actual populations.

The multicollinearity test aims to test whether the regression model found a correlation between the independent variables. The presence or absence of multicollinearity in the regression in this study was tested with the Variance Inflation Factor (VIF). The test results show that the tolerance value is less than 10 and the tolerance value is more than 0.1. It means that there is no multicollinearity problem.

The heteroscedasticity test aims to test whether in the regression model there is an inequality of variance from the residuals of one observation to another. In this study, the Glejser test is used. The provisions are that if the independent variables have no heteroscedasticity symptoms with statistically significantly more than 0.05.

### 3.6. Data Normality And Validity And Reliability Test

The data normality and validity and reliability test were executed using a statistical test. The data normality test used in this study was the Kolmogorov-Smirnov test data normality. The test criterion is that if the significance value is more than 0.05. All the data in this study has normally distributed with a significance value is less than 0.05 then the data is not normally distributed.

The validity test in this study was carried out using the Pearson correlation method with a cut-off value greater than the r table (critical value). All the instrument in this study is declared valid with each item obtaining a calculated r value greater than r table.

The reliability test aims to measure the reliability of the questionnaire which is an indicator of the variable. In this research, the

author uses Cronbach's Alpha  $\geq 0.6$ . The results of the reliability test show that each variable passes the criteria means that the instrument used in this study is reliable.

## 4. Result

### 4.1. Descriptive Statistics

The demographic characteristics of respondents are classified into, sex, age, education, and employment. Based upon sex, respondents of this research are male 34.4% and female 65.6%. Based on employment; housewives 15.6%; private employment 24.0% students as much as 6.3 %; government officials much as 29.2% entrepreneurs as much as 25.0%. Based on education; Senior high school 12.5% Diploma as much as 30.2% Bachelor 57.3%.

### 4.2. Hypothesis Testing

Hypothesis testing aims to determine the significant effect of the independent variable on the dependent variable. In this study, the hypothesis test was conducted by using the t-test. Ghozali (2013: 90) states that the t-test in multiple linear regression analysis aims to determine whether the independent variable (X) partially has a significant effect on the variable (Y). Testing on this partial hypothesis test uses a significance level of 5%, then the testing criteria is if the significance value  $t < 0.05$ , then there is a significant influence between one independent variable on the dependent variable, whereas if the significance value  $t > 0.05$ , then there is no significant effect between the independent variables on the dependent variable. The multiple linear regression results are presented in Table 1.

Based on Table 1, the resulting regression model as an explanatory model for the effect of HS, FI and SE on IB at the Rien Collection Jember fashion store can be stated as follows:

$$Y = 1,012 + 0.396 HS + 0.306 FI + 0.216 SE + e$$

- a. **Constant Value**  
 From the equation above, a positive value is obtained at a constant of 1.012, which means that if hedonic shopping (HS), fashion involvement (FI), and store environment (SE) are equal to zero, low quality of purchasing (IB) have a positive value of 1.012.
- b. **HS (hedonic shopping)**  
 The coefficient value of the HS variable is positive with a value of 0.396, which means that the higher the HS, the more impulse-buying consumers at the Rien Collection Jember fashion store will experience an increase. The HS variable in this study is the variable with the greatest influence on low quality of purchasing
- c. **Fashion Involvement (FI)**  
 The coefficient value of the fashion involvement variable is positive with a value of 0.306, which means that the higher the fashion involvement, the higher the of consumers at the Rien Collection Jember fashion shop.
- d. **Store Environment (SE)**  
 The coefficient value of the store environment variable is positive with a value of 0.216, which means that the better the store environment, the IBof consumers at the Rien Collection Jember fashion store will increase.

**Table 1.** Results of Multiple Linear Regression Analysis (Researcher analysis., 2022)

Variable	Regression Coefficient	Sig.	Information
a	1,012	-	-
<i>Hedonic Shopping (HS)</i>	0.396	0,000	Significant
<i>Fashion Involvement (FI)</i>	0.306	0.001	Significant
<i>Store Environment (SE)</i>	0.216	0.015	Significant

Note: the dependent variable is Low quality of purchasing (LQP)

**Table 2. The t-test results**

Variable	T count	T table	Sig.	Information
<i>HS</i>	4,800	1,986	0,000	Not to accept H0
<i>FI</i>	3,563	1,986	0.001	Not to accept H0
<i>SE</i>	2,489	1,986	0.015	Not to accept H0

Based on Table 2 can be explained the effect of each variable. The results of testing the effect of the HS variable on IB obtained t-statistics = 4,800 > t table = 1.986 with a p-value = 0,000 < 0.0. This means that not accepting H0 and accepting Ha, meaning that HS had an effect. significant towards IB on consumers of the Rien Collection Jember fashion store.

The influence of the FI variable on the IB obtained a t-statistics = 3.563 > t-table = 1.986 with p-value = 0.001 <  $\alpha$  = 0.05 so that H0 is rejected. And accepting Ha influences FI towards IB on consumers of the Rien Collection Jember fashion store.

The SE variable on IB obtained a t value of 2.489 which is greater than the t table, namely 1.986 and a significance value of p-value = 0.015 <  $\alpha$  = 0.05 so that not accepting H0 and accepting Ha meaning that the SE has an effect significant towards IB on consumers of the Rien Collection Jember fashion store.

## 5. Discussion

### 5.1. Effect of Hedonic Shopping on Low quality of purchasing

*The Hedonic Shopping* effect on Low quality of purchasing on consumers of the Muslim

fashion store Jember is evidenced by the results of the t-test which shows t-statistics greater than the t table (4,800 > 1,986) p-value  $\leq \alpha, 5\% = 0,000 < 0.05$ . The relationship shown by the coefficient value is positive, indicating that the higher the hedonic shopping level, the more consumers at the Muslim Fashion store Jember will increase. The results of this study are in line with previous research conducted by (Kim et al., 2012; Parsad et al., 2021) hedonic shopping has a significant effect on low quality of purchasing.

To create Hedonic Shopping for consumers, The Muslim Fashion store Jember seeks to create shopping emotions in consumers so that consumers will feel happy when shopping by providing complete products and facilities at the store so that consumers will be willing to linger in the shopping centre. Muslim Fashion store Jember also often holds sales discounts to increase consumers' Hedonic Shopping behaviour to create low quality of purchasing.

Based on the description of the research variables, it is found that consumers of the Muslim Fashion store Jember Clothing store have quite high hedonic shopping behaviour so the possibility of low quality of purchasing that consumers will make will also be higher.

Hedonic shopping in this study is measured through eight indicators consisting of novelty fun, praise from others, escapism, social interaction, money availability, time availability, and task definition. While low quality of purchasing (IB) is measured through four indicators consisting of spontaneity, out-of-control, non-cognitive evaluation, and disagreement of consequences.

In terms of the relationship between the two variables; the first indicator regarding novelty, many respondents, consider that the Muslim Fashion store Jember fashion store provides fashionable clothing products; this makes consumers buy a product even though they don't need it. Muslim Fashion store Jember always strives to provide trendy products because they are the target of consumers to make them look attractive, unique or cool.

The second indicator regarding fun, is that many respondents think that they feel quite happy when shopping at the Muslim Fashion store Jember. The many type of fashion products displayed impulse freely chooses the products according to their wishes.

The third indicator regarding praise of others is that most respondents think that a feeling of pride arises when using the products of the Muslim Fashion store Jember. The fashion sell the unique products that are not sold in other stores; this makes the product not impressed by the market so that the wearer will feel proud to use the product he bought.

The fourth indicator concerns escapism; most respondents think that the feeling of fatigue is quite lost when shopping at the Muslim Fashion store Jember. Feelings of fatigue can disappear when a consumer sees a lot of good, unique and attractive fashion products so that even though consumers are in the Muslim Fashion store for a long time, they will still feel happy because they can see and buy the products offered.

The fifth indicator is about social interaction; most respondents think shopping at the Muslim Fashion store Jember with friends is enough to increase intimacy; this makes a comfortable impression so that consumers are willing to linger in the store and make purchases without being planned because they are interested in something. product. Shopping with other people will certainly make a consumer able to discuss how to assess the fashion product that he will buy so that it will certainly create intimacy.

The sixth indicator regarding money availability is that most respondents perceive that shopping at the Muslim Fashion store Jember Clothing Store is done when they have enough money; this makes consumers not consider risks after purchasing fashion products at the store. The products offered by the Muslim Fashion store Jember relatively expensive. When consumer comes to this shop, they have to provide enough money to get the product they want and immediately buy it without thinking about the risk.

The seventh indicator regarding time availability; is the majority of respondents think that there is enough free time to shop at the Muslim Fashion store Jember Clothing Store, which makes consumers not rush to select the products and make a purchases without a plan. Consumers who are willing to linger in the Muslim Fashion store Jember fashion store will certainly see a lot of the products offered so they are more likely to make unplanned purchases.

The eighth indicator regarding task definition; is the majority of respondents think that sometimes there is a desire to shop at the Muslim Fashion store Jember Clothing Store when they see attractive promos so that consumers will immediately buy the product without thinking about the usefulness of the product being purchased. Promotion is the most powerful strategy to attract consumers; when Muslim Fashion store Jember provides promotions such as

discounted prices, consumers will be interested and want to buy these fashion products because the opportunity to get these products at a lower price is unlikely to happen next time.

## 5.2. Effect of Fashion involvement on Low quality of purchasing (LQP)

*Fashion involvement* effect on low quality of purchasing on consumers of the Muslim Fashion store Jember clothing store is evidenced by the results of the t-test which shows t-statistics is greater than the t table ( $3.563 > 1.986$ )  $p\text{-value} \leq \alpha$ ,  $5\% = 5\%(0.001 < 0.05)$ . The relationship shown by the coefficient value is positive indicating that the higher the fashion involvement, the more low quality of purchasing consumers at the Muslim Fashion store Jember will increase. The results of this study are in line with research conducted by (Nimmermann, 2019; Triwijayati et al., 2020; Vinish et al., 2020) showing that fashion involvement has a significant effect on decision making process.

Based on the description of the research variables, it is found that consumers of the Muslim Fashion store in Jember have a fairly high fashion involvement behaviour so that the possibility of low quality of purchasing that consumers will make will also be higher. Fashion involvement in this study is measured through four indicators consisting of important fashion probability or chance of error in purchasing, fashion showing a characteristic or a symbol, and pleasure in fashion. While low quality of purchasing is measured through four indicators consisting of spontaneity, out-of-control, non-cognitive evaluation and disagreement of consequences.

The following is the relationship between the two variables; (1) The first indicator is the first indicator regarding with fashion appearance that must be maintained to support daily activities. This makes

consumers willing to make unplanned purchases when they see the latest fashion products at the Muslim Fashion store Jember Clothing store. Appearance needs to be maintained by someone to make it look attractive than others. Consumers will strongly desire to buy fashion to judge that they look beautiful or handsome.

The second indicator is about the probability or chance of error in buying. The majority of respondents think that they feel quite confused when making choices when buying fashion products at the Muslim Fashion store Jember Clothing Store because of the availability of various attractive clothing choices so that consumers make purchases without prior consideration of the benefits of the clothes they buy. Consumers will immediately buy the product they want without thinking about the risks they expect, although when buying the product they want, consumers feel confused about choices.

The third indicator regarding fashion shows a characteristic or a symbol; eeeee majority of respondents consider the fashion products of the Muslim Fashion store Jember to adequately reflect their own style. This is important because of the attractive and comfortable design to use becomes focus of concern of the fashion products. The products offered at the Muslim Fashion store Jember are always up to date, which makes consumers want to buy them so that they can be seen as stylists.

The fourth indicator regarding the pleasure of fashion; the majority of respondents think that using fashion at the Muslim Fashion store Jember Clothing Store is enough to create pleasure, so consumers want to have fashion products offered at the store and buy them without looking at the quality of the materials but seeing the design side. The products offered at the Muslim Fashion store Jember are always up to date, which makes consumers want to purchase and keep stylists.

The fourth indicator regarding the pleasure of fashion; the majority of respondents think that using fashion at the Muslim Fashion store Jember Clothing Store will create pleasure. Accordingly, consumers interested to buy products offered at the store and creates buying based upon the design. The products offered at the Muslim Fashion store Jember are always up to date, which makes consumers seen as stylists. The fourth indicator regarding the pleasure of fashion; the majority of respondents think that using fashion at the Muslim Fashion store Jember Clothing Store is enough to create pleasure, so consumers want to have fashion products offered at the store and make a purchase

### 5.3. The Effect of Store Environment on Low quality of purchasing (LQP)

*Store environment* effect on low quality of purchasing on consumers of the Muslim Fashion store Jember clothing store is evidenced by the results of the t-statistics which shows t-statistics greater than the t-table ( $2.489 > 1.986$ )  $p\text{-value} \leq \alpha$ ,  $5\% = 5\%$  ( $0.015 < 0.05$ ). The relationship shown by the coefficient value is positive, indicating that the better the store environment is, the low quality of purchasing of consumers at the Muslim Fashion store Jember fashion store will increase. The results of this study are in line with research conducted by Tendai and Crispen (2009), Mohan et al., (2013), Saad and Metawi (2015), Wulandari (2018) and Raihani (2019) showing that the store environment has a significant effect on low quality of purchasing.

Based on the description of the research variables, information is obtained that consumers of the Muslim Fashion store Jember Clothing store have a fairly good store environment behavior, so the Low quality of purchasing that consumers will make will also be higher. The store environment in this study is measured through four indicators consisting of music

(X3.1), lighting (X3.2), layout (X3.3) and employees (X3.4).

The first indicator regarding music, the majority of respondents think that the music at the Muslim Fashion store in Jember Clothing Store is sufficient to generate interest in visiting; this encourages consumers to buy a fashion product that was not planned in advance. The Muslim Fashion store Jember fashion shop always plays songs to create comfort for consumers; this also indirectly makes consumers feel at home to linger in the store.

The second indicator is about lighting; most respondents think that the lighting at the Muslim Fashion store Jember Clothing Store is designed well enough to make it easier to shop and create a sense of comfort that makes consumers more likely to make purchases without strong effort. Lighting in a fashion store is certainly an important thing so that consumers can easily see in detail the products they are going to buy and make it easier for consumers to find the products they want.

The third indicator is about the layout; the majority of respondents think that fashion products in the Muslim Fashion store Jember Clothing Store are grouped by type so that it gives a pretty neat impression and makes consumers easy to choose the desired fashion product and is likely to buy the fashion product they like without looking ingredients of the product. The arrangement at the Muslim Fashion store Jember fashion store is done neatly and is grouped by type so that consumers will easily find the product they are looking for. The fourth indicator regarding employees; the majority of respondents think that employees at the Muslim Fashion store Jember Clothing Store provide quite a friendly service; this creates a comfortable impression when shopping and makes consumers willing to buy the fashion products offered without prior planning. Good employees will certainly make consumers feel comfortable and

enjoyable on finding the product they want.

## 6. Conclusion

Based on the analysis of hedonic shopping, fashion involvement, store environment and low quality of purchasing variables, the conclusions of this study are as follows.

- a. *Hedonic Shopping* effect on low quality of purchasing on consumers of the Muslim Fashion store Jember fashion store. The Muslim Fashion store Jember fashion store seeks to create hedonic shopping by building shopping emotions in consumers so that consumers are willing to do shopping and make low quality of purchasing.
- b. *Fashion involvement* effect on low quality of purchasing on consumers of the Jember muslim fashion store. The store provides a variety of fashion and is always updated so that consumers who see this new product will like it and want to buy it even though it was not planned beforehand.
- c. *Store environment* effect on low quality of purchasing on consumers of the Muslim Fashion store Jember fashion store. The store environment in this store were well managed so that consumers feel at home in the store; with a comfortable shop atmosphere, consumers will linger in the store and are likely to see fashion products on display which will create low quality of purchasing.

## 7. Research Limitations

Based on the results of this study, there are limitations of this study that are the consumers population are limited to

consumers who are in the Muslim Fashion store Jember Stores only. In addition, this study were using offline survey that are limitted number of sample reached during the periods of research.

## 8. Recommendation

Based on the results of this study, the suggestions that can be given to several parties include the following:

- a. For the owner of the Muslim Fashion store  
The owner of the Muslim Fashion store should pay attention regarding hedonic shopping on the fun indicator. The business owner can create a pleasant atmosphere by providing attractive sales promotion such as package discount. With regards to fashion involvement on the fun indicator for fashion, the owner expected to provide up-to-date fashion designs that always trendy in order to attack towards the product fashion offered. In connection with the store environment in oarticular layout indicator, the usiness owner needs to imprpve the layout of the fashion and easily looking out the clothes.
- b. For Further Researchers  
For future researchers, it is better if the research is more generalized by expanding the object of research in the Muslim Fashion store in other countries. Researchers are also encouraged to add aother variables to improve management strategies to reach consumer high quality of purchasing. Future researchers also need to use omni channels to make it paperless and to reduce errors in inputting research data.

## A CASE STUDY ON THE SURVEY BASED RESEARCH OF CUSTOMER'S CHOICE OF TOOTHPASTE IN RAJASTHAN'S POPULATION

**Abstract:** *Toothpastes are essential part of dental hygiene and help prevent multiple and widespread tooth and gum diseases. The customer's choice of toothpaste sheds light on this knowledge of dental hygiene among the customers of various ages, sexes, ethnicity, financial statuses, geographical locations, etc. In present article, a survey was conducted among 300 people from different parts of Rajasthan. The questionnaire used was kept consistent and covered various aspects to generate ultimate customer satisfaction, while assessing future needs and satisfaction level of consumers. Results have been evaluated with the help of pie charts and further evaluation and studies on them have been done to give detailed conclusion. The information can help understand the type of oral hygiene methods that patients feel comfortable to approach and use. It can also help to understand the knowledge level of patients regarding dental hygiene.*

**Keywords:** *Toothpaste; Oral hygiene; Dental care; Oral hygiene aids; Dental carries*

### 1. Introduction

Although preventable, dental caries continues to be the most common non communicable disease worldwide. As much as 80% of caries incidence is experienced by only 20–25% of children, with 10% having untreated cavities, and those from low socioeconomic and minority groups experiencing significantly higher rates and at younger ages. [14]

Toothpastes are highly complex semisolid pastes that contain several active ingredients. Starting off with abrasives to remove dental plaque as effectively as possible. Many different abrasives are used in toothpastes, for example, hydrated silica, calcium carbonate, calcium phosphates, perlite,

alumina, and sodium bicarbonate. Different abrasives differ in relative hardness values and consequently in their cleaning efficacy and abrasion properties. In general, there is a trend of improvement to highly efficient abrasives, which show good plaque disruption or removal abilities, while having reduced radioactive dentin abrasion (RDA) values. [15]Fluoride has been identified as a potent caries preventive agent with significant benefits. Daily brushing with fluoride toothpaste is the most common topical fluoride application method. However, there are problems associated with fluoride applications, such as toxicity at high doses. The availability of fluoride over the past few decades has now led to the evolution of fluoride-resistant *S. mutans* and

other oral bacterial species; hence, its actions on acid-producing microbes may be diminishing. [18]

In addition to delivering therapeutic agents to combat caries and gingivitis, toothpastes are formulated to remove dental plaque, as well as stains, as effectively as possible while being gentle to teeth and gingiva. [15]

This survey discusses the factors that influence the customer's choice, this information can help understand the type of oral hygiene methods that patients feel comfortable to approach and use. It can also help to understand the knowledge level of patients regarding dental hygiene. [1] Prevention of oral disease is considered to be the most effective, acceptable and efficient method to attain oral health. The attitude of people toward their own teeth, and the attitude of dentists who provide dental care, play an important role in determining the oral health condition of the population. [2] There seems to be a lack of knowledge and awareness about how to choose a dentifrice and toothbrush, so education of people on the importance of oral hygiene maintenance, proper selection and method of use of oral hygiene products is needed. [3]

Consumer behavior is not exactly predicted one; somewhat it is predicted with the help of research activity. Starting and ending of the survey ends with only one statement 'consumer is king'. So the companies concentrate in analyzing the requirement of people thoroughly to satisfy and retaining the consumer. [4]

Previous experience seems to be a very strong factor in the choice of both the toothbrush and toothpaste in a study, which suggest that for as long as the respondents are satisfied with a particular product, they will stick to it. [5]

Another factor that may go a long way in determining the choice of toothpaste by a consumer is the content of the paste. Some consumers are concerned with the herbal contents, while others are concerned about

the fluoride content. Anecdotal reports have it that the majority of consumers of toothpaste in Nigeria are more concerned about the herbal content, while the dentists are those more concerned about the fluoride content. [6, 7]

Herbal tooth pastes have similar antibacterial effect as conventional tooth pastes. Tooth paste with multiple herbal ingredients is more efficient than the tooth pastes with fewer herbal ingredients in an anticariogenic property. [8] Although, homemade toothpaste seems dangerous, a study evaluating 84 homemade formulations stated that none of the formulas analysed contained any fluoride salts also highlighting that it is impossible to predict their abrasiveness and microbiological quality. [12]

There is a need for the dental professionals to be aware of the ever-increasing development and marketing of oral hygiene products from various databases. Hence, the education of people regarding the importance of oral hygiene maintenance, proper selection of oral hygiene products is essential. [9]

In present study, customer expectations, usage, attitude and brand comparison were studied for the toothpaste category, wherein the primary benefits that the consumer seeks while using a particular brand was analyzed with its purchasing pattern and behavior, and the core triggers to purchase their favorite brand. The effect of demographic factors like age, gender, occupation, income level was observed with respect to the purchase of toothpaste. Switching behavior between various brands was analyzed with the help of factors like offering attractive discounts, use of samples, price points and availability. [10]

## 2. Material & Methods

Problem formulation: The survey addresses only what the participants answered based on their personal experiences. The number is only limited to 300 people due to limited

reach of researchers involved, despite that the survey covers all regions of state widely. A cross sectional study was conducted among 300 people from different parts of India. Questionnaires were distributed to all subjects of various age groups, gender, ethnicities, financial backgrounds and geographical locations.

Consumers choose their options among the various choices given below the questionnaire. The following gives the list of questions and the respective answer depicted in the pie chart.

**Figure 1.** What is the brand of toothpaste that you are using at present?

**Figure 2.** Which flavour of toothpaste do you prefer?

**Figure 3.** After how long does the flavour of toothpaste recede from your mouth?

Figure 4. Do you buy toothpastes in stock or when needed?

**Figure 17.** Is your current brand prescribed by a dentist?

**Figure 18.** Have you used any natural brushing aids?

**Figure 19.** Do you change your toothpaste regularly?

Figure 20. If Yes, why?

Figure 21. Does the cost of the toothpaste affect your selection?

Figure 22. Do you believe packaging, advertisement or cost has nothing to do with the quality of the paste?

Figure 23. Does foaming action in your toothpaste affect your choices?

### 3. Result

A total of 23 questions were included in the survey. The first question addressed the brand being used at present by most customers and 39% customers agreed to using brands like Patanjali, Himalaya, Dabur, Sensodyne, Vico. The most common reason for choosing a brand was found to be Flavour as 62.3% of the population prioritises it. In another question, taste of toothpaste was not found to be a huge factor as 54.7% customers were either not affected by taste at all or it wasn't a significant factor for them, although peppermint holds the most preferred flavour spot with 57.3% votes. For about 38.3% of people, this taste recedes within 5 minutes of brushing.

Mouthwashes play an important role in dental hygiene, yet 81% of the population doesn't use them, moreover 5% of the population doesn't know of the presence of such aids in market. Similarly, toothpastes for children are unknown to 60.3% population. 89.1% need more awareness about dental hygiene as they find their current knowledge lacking. About 30% of the population has not given consideration to their dental health, and 44.7% use good quality toothpaste to prevent decay. Amount used commonly is as much as the length of their brush head for 46% people. For about 60% of the population brushing and whitening of teeth are not correlated and only 2 people in the entire population had undergone bleaching to whiten their teeth.

Herbal toothpastes have had more share in the market now than ever, it is seen as 66.7% of the population have used herbal toothpaste at least once. Yet natural brushing aids uses were limited to 18% of population. About 72.7% of the population doesn't consult a dentist for the choice of their toothpastes.

About 50% customers have been using the same brand since 1 to 2 years, and more than 37% have been using their brands for more

than 5 years. Brand loyalty again comes into play as 87.7% of the population doesn't change their toothpaste brands regularly. Out of 12.3% that actually do change, it's mostly for reasons other than dentist recommendations, advertisements and results of toothpastes. Only 15.6% of the population gives importance to results of toothpaste before changing brands and 16.9% value advertisement as a factor for brand switching.

About 66% of people were unconcerned with the price of their toothpastes. Only 12% have bought them as gifts or amenities. Packaging, advertisement or cost can have association with quality of product divided the population as 50% votes were for either option. About 67% population stocks up on one or other kind of packages, most popular ones being family packs with 47% votes. 53% people brush once a day.

Future trends suggest, antimicrobial action (35.9%), fluoride free nature (25%) and organic ingredients (25%). 67.6% customers wished for paste consistency over gel. Foaming action can affect brand selection too and about 60.6% customers agreed to foaming ability affecting their choices. Customer satisfaction is the ultimate goal, and 78.6% seem adequately satisfied with their current choices.

### 4. Conclusion & Future Aspect

Decreasing trust for various ingredients used in industry has led to development of a trend and consequently the herbal products demand started growing. Dabur has first mover advantage in market, after that came brands like Himalayas and Patanjali, who have gained unique position as well. With increasing acceptance of herbal products by consumers various MNE's like Colgate, HUL and P&G have realised the demand and have launched various herbal products for the same.

Excess fluoride consumption while teeth are developing can result in visibly detectable changes in enamel structure such as discoloration and pitting. Therefore, Centers for Disease Control and Prevention recommends that children should start using fluoride toothpaste at age 2 years. Children aged <3 years should use a just the size of a rice grain, and children aged >3 years should use no more than a pea-sized amount (0.25 g) until age 6 years. Although in an in vitro study the cleaning efficacy of medium-abrasive toothpaste showed that 1.00 g has a significantly higher cleaning efficacy than 0.25 g toothpaste and 0.125 g toothpaste. Rajasthan's population should be made aware of need for children specific toothpastes and amount they have been using. To solve the problem of excess fluoride content being used in toothpastes, 10% hydroxyapatite can provide comparable efficacy with in remineralizing initial caries

and preventing demineralization. Also incorporation of 2% arginine into fluoride toothpaste significantly increases its remineralization properties, as demonstrated by increased mineral gain, percent remineralization, surface Ca/P ratio with fluorine concentration, and enamel fluoride uptake.

Although the qualities like flavouring and foaming are important for consumer satisfaction but these should not be the whole and sole selling point for pastes. Proper advice from a trusted dentist should be taken before purchasing a tooth paste.

**Acknowledgment:** We grateful thanks to all the sincere and extremely helpful friends for their support and help for the completion of work. Last but not the least, we thankful to all those who cooperated and helped me directly or indirectly to carry out this work.

## THE EFFECT OF PRODUCT QUALITY AND STORE ATMOSPHERE ON CUSTOMER LOYALTY THROUGH CUSTOMER SATISFACTION AT ALFAMART JEMBER

**Abstract:** This study aims to analyze and examine the effect of product quality and store atmosphere on customer loyalty on customer satisfaction at Alfamart Jember. The population in this study, all customers at Alfamart Summersari District, which are on Kalimantan Street and MT Haryono Street, and Alfamart Patrang District, which are chosen are Alfamart PB Sudirman Street and Alfamart Dr. Soebandi Street and Alfamart Kaliwates District, which are located at Ahmad Yani Street and at Basuki Rahmat Street. The results showed that product quality had a significant effect on customer satisfaction, product quality had a significant effect on customer loyalty, store atmosphere had a significant effect on customer satisfaction, and store atmosphere had a significant effect on customer loyalty. The findings of this study customer satisfaction have a significant effect on loyalty customer, product quality has a significant positive effect on customer loyalty through customer satisfaction and Store atmosphere has a significant positive effect on customer loyalty through customer satisfaction. Suggestions to add other variables, brand image, price, service quality, sales promotion, focused repurchase interest, and customer loyalty.

**Keywords:** Product Quality, Store Atmosphere, Customer Satisfaction, Customer Loyalty.

### 1. Introduction

The retail industry can be defined as an industry that sells products and directly provides services to end consumers (Berman and Evan, 2007:544). Most of the products sold are daily household needs using a self-service system, where consumers take their products or goods without being assisted by serving salespeople. The growth of retail business sales in Indonesia in the last few years from 2013-2021 has experienced quite an increase and decrease. Data in 2021 shows

retail sales growth in Indonesia by 9.8%. The record increased compared to the previous year, namely -14.6%. The data hit a record high of 15.2% in 2013 and a record low of -14.6% in 2020 (CEICdata.com). The growth of retail sales in Indonesia from 2013-2021 can be seen in Table 1. Table 1 shows that growth in Indonesia fluctuates every year. Seen in 2020 there was a very drastic decline in retail sales growth in Indonesia. The decline in retail growth in 2020 was due to the Covid-19 pandemic.

**Table 1.** Retail Growth in Indonesia in 2013 - 2021

No	Year	Retail Growth Each Year (%)
1	2013	15,2 %
2	2014	10 %
3	2015	5 %
4	2016	6,3 %
5	2017	-3,5 %
6	2018	-2,5 %
7	2019	-8 %
8	2020	-14,6 %
9	2021	9,8 %

Source: www.ceic data.com, 2021

The Indonesian Retail Entrepreneurs Association (APRINDO) said growth in 2020 only reached 3-3.5% or weakened compared to last year which ranged from 8%-8.5% (CEIC Data, 2020). The government's implementation of Large-Scale Social Restrictions (PSBB) has weakened retail growth. Even though shopping centers or malls have been opened, sales of modern retail stores have not met the expectations of business actors. The impact of the PSBB has also made people's purchasing power decline, thus holding back the pace of sales. The operational duration of several modern retail stores in Indonesia is also still limited to 6 hours from the previous 12 hours (<http://katadata.co.id>, 2020).

Alfamart is one of the retail companies that is experiencing fairly rapid development in Indonesia today. Alfamart is widely spread throughout Indonesia, one of which is Jember. Jember has 31 sub-districts, including Summersari District, Patrang District, and Kaliwates District, there are 131 retail units Alfamart in Jember Regency. The surge in modern retail in Jember has made competition between retail companies increasingly fierce, so retail entrepreneurs have their own ideas to find consumers so that they are interested in buying Alfamart products.

Alfamart retailers strive to increase competitiveness in the market by developing store brands. Alfamart is one of the retail outlets in Jember, making Alfamart the choice for people to shop for their daily needs at affordable prices and provide products from well-known companies, but also provide products with their brand Alfamart own, such as snacks, water, minerals, tissue, cooking oil, rice, and other household utensils. Alfamart realizes that a competitive advantage can be achieved by developing private label brands. Private labels are products marketed and developed by retailers that are only sold in stores retail (Levy and Weitz, 2007: 610). The advantage of having a private label is to strengthen customer loyalty, flexibility in pricing, and have control over the quality of goods.

Product quality is an important factor that is considered to obtain customer satisfaction after buying and using the product. Similarly, what Alfamart does to continue to capture market share by seeking customer satisfaction through the quality of products, private label among others, is the presentation of products private label that have attractive visual presentations so that they are appetizing, the arrangement of each product private label looks neat and in place, and the services provided by Alfamart employees are friendly and fast. The quality of these products will certainly affect consumer satisfaction. Research conducted by Nasirudin, Yulisetiari, and Suroso (2018) shows that product quality has a significant effect on customer satisfaction. According to Wirawan, Sjahrudin, and Razak (2019), that product quality has a significant effect on customer satisfaction. Syahmi, Colia, and Warman (2021) state that product quality has a significant effect on customer satisfaction. This means that the better the quality of the available products, the better the customer satisfaction. According to Ariescy, Yulisetiari, and Dimiyati (2017) who state that product quality has a positive effect on customer loyalty. Good product quality will

affect customer loyalty to the product. According to Wulandari, Hufron, and Basalamh (2020), Gunawan, Fathorrahman, and Handoko (2019) showed the same results that product quality had a significant effect on customer loyalty.

Store atmosphere plays an important role because of the environment that influences consumer behavior. Customers think that shopping is a form of recreation if a place makes them feel peaceful, comfortable and wants to linger in that place. Likewise, Alfamart, which makes a minimalist concept with a red display in almost all parts of Alfamart stores. The red color is believed to evoke feelings of pleasure and joy so that customers who come to Alfamart will not feel bored and feel at home in the store for a long time. Store atmosphere also has the same role to boost the customer in creating customer satisfaction. Research conducted by Winarjo and Japariato (2017) proves that store atmosphere has a significant effect on customer satisfaction, where the room design and layout are neatly arranged, lighting is very good, and access in and out that facilitates customer activities will make customers feel comfortable. In line with the research of Kumala, Hufron, and Khalikussabir (2020), Yulisetiari and Mawarni (2021) showed that the Store Atmosphere had a significant effect on customer satisfaction. In addition, according to Winarjo and Japariato (2017), the results show that store atmosphere has a significant effect on customer loyalty. In line with the research of Gunawan et al. (2019), Yulisetiari and Mawarni (2021) show the same result that Store Atmosphere has a significant effect on customer loyalty.

## 2. Literature Review

### 2.1 Product Quality

Product quality is something that has a good or bad level consisting of all the factors attached to the product, so that the product has the ability to be used as desired by consumers, therefore high product quality is needed so that satisfaction can be fulfilled (Kotler and Keller, 2012). According to, Orville, Larreche, Boyd (2005) formulate the dimensions of product quality are as follows.

1. Performance
2. Durability
3. Conformance to specification
4. Features
5. Reliability
6. Aesthetics
7. Perceived quality
8. Serviceability

### 2.2 Private Label

According to Keller (2007) private labels have become premium brands that have been known in European countries since 1990, so sometimes superior in terms of quality to the manufacturer's brand. Private labels are products that are marketed and developed by retailers and are only sold and available in stores retail (Levy and Weitz, 2007). Private label is divided into 4 product lines, namely personal care, food, nonfood, household (Beldona and Wyong, (2007).

### 2.3 Store Atmosphere

The store atmosphere is a combination of several elements of the store's physical characteristics such as coloring, temperature, architecture, sound, lighting, sign and layout, where all of these elements create a company image in the minds of customers or shop visitors (Berman and Evan, 2007). The store atmosphere is an environmental design through music, fragrances, visual communication, lighting, and colors to influence customers to buy an item and design

an emotional response to customer perception (Utami, 2010). Chatterjee, Berman, and Evans (2018), states that the store atmosphere is divided into 4 elements, namely.

1. Exterior Variable
2. Interior Variable
3. Store Layout
4. Interior Point of Purchase

### 2.4 Customer Satisfaction

According to Yulisetiari *et al.* (2020), customer satisfaction needs attention to the response of a product or service offered, basically, satisfaction is the goal of the company. Feelings of pleasure or disappointment from someone arising from comparing products (or results) against their expectations with perceived performance are called satisfaction (Kotler and Keller, 2009). Tjiptono (2007) says that the factors that influence consumer satisfaction are as follows.

1. Conformance of expectations
2. Ease of obtaining
3. Feelings after using

### 2.5 Customer Loyalty

Loyalty is a deeply held commitment to buy or re-support a preferred product or service in the future despite situational influences and marketing efforts that cause customers to switch (Kotler, 2016). Customer loyalty is a consumer who is strongly committed to buying or subscribing to a particular product or service in the future (Kotler and Keller, 2009b). According to Parasuraman, Zeithaml, and Berry (2009), indicators of strong loyalty are.

1. Say positive things about the company
2. Recommend the company to someone who seeks advice
3. Continue purchasing

## 3. Methodology

The population of this study, all customers at Alfamart Sumbersari District, namely Alfamart Jalan Kalimantan and Alfamart Jalan MT Haryono, Alfamart Kecamatan Patrang, namely Alfamart Jalan PB Sudirman and Alfamart Jalan Dr. Soebandi and Alfamart Kaliwates District, namely Alfamart Jalan Ahmad Yani and Alfamart Jalan Basuki Rahmat. The sampling technique used non-probability sampling with the purposive sampling method. The sample used was 120 respondents with a minimum age of 17 years who had visited, and made purchases and consumer products private label at least 2 times during the last month. The source of data in this study is primary data from data collection using a questionnaire via a google form. The analytical method used is path analysis.

## 4. Results and Discussion

### 4.1 Hypothesis Test

The following are the results of hypothesis testing in the study based on Table 2 below.

**Table 2.** Hypothesis Test Results

Hypothesis	Sig.	Description
$X_1 \rightarrow Z$	0,004	H <sub>1</sub> accepted
$X_2 \rightarrow Z$	0,000	H <sub>2</sub> accepted
$X_1 \rightarrow Y$	0,000	H <sub>3</sub> accepted
$X_2 \rightarrow Y$	0,011	H <sub>4</sub> accepted
$Z \rightarrow Y$	0,000	H <sub>5</sub> accepted

Source: Processed, 2021

- a. The effect of product quality on customer satisfaction

Based on Table 2 it can be seen that the results of testing the effect of product quality variables on customer satisfaction have a significance value of 0.004, then the value is smaller than 0.05 so it can be concluded that H<sub>0</sub> rejected and H<sub>1</sub> accepted which means that the quality product has a significant positive

effect on customer satisfaction at Alfamart Jember.

b. The effect of store atmosphere on customer satisfaction

Based on Table 2 it can be seen that the results of testing the influence of the variable store atmosphere on customer satisfaction have a significance value of 0.000, then the value is smaller than 0.05 so it can be concluded that  $H_0$  rejected and  $H_2$  accepted which means that the store atmosphere has a significant positive effect on customer satisfaction at Alfamart Jember.

c. Effect of product quality on customer loyalty

Based on Table 2 it can be seen that the results of testing the effect of variable quality products on customer loyalty have a significance value of 0.000, then the value is less than 0.05 so that we can conclude  $H_0$  rejected and  $H_3$  accepted, which means that the quality product has a significant positive effect on customer loyalty at Alfamart Jember.

d. The effect of store atmosphere on customer loyalty

Based on Table 2 it can be seen that the results of testing the influence of the variable store atmosphere on customer loyalty have a significance value of 0.011, then the value is smaller than 0.05 so it can be concluded that  $H_0$  rejected and  $H_4$  accepted which means that the store atmosphere has a significant positive effect on customer loyalty at Alfamart Jember.

e. The effect of customer satisfaction on customer loyalty

Based on Table 2 it can be seen that the results of testing the influence of the customer satisfaction variable on customer loyalty have a significance value of 0.000, then the value is smaller than 0.05 so it can be concluded that  $H_0$  rejected and  $H_5$  accepted which means that satisfied customers have a significant positive effect on customer loyalty at Alfamart Jember.

#### 4.2 Path Analysis

- 1) The indirect effect of product quality on customer loyalty through customer satisfaction is  $0.242 \times 0.393 = 0.095 = 9.5\%$
- 2) The indirect effect of store atmosphere on customer loyalty through customer satisfaction is equal to  $0.567 \times 0.393 = 0.222 = 22.2\%$

Figure 1. Path Analysis Results

Based on the calculation of the path coefficient, the results can be described as follows.

a. The effect of product quality on customer loyalty through customer satisfaction.

Based on the calculation results, it can be seen that the direct effect of product quality on

customer loyalty is 0.296 or 29.6%, greater than the indirect effect of 0.095 or 9.5%, which shows that if the value of direct influence > indirect effect, which means that indirectly product quality has a significant effect on customer loyalty through customer satisfaction. The value of the direct influence path coefficient is greater, then product quality has a greater effect on customer loyalty than having to go through customer satisfaction.

- b. The effect of store atmosphere on customer loyalty through customer satisfaction.

Based on the calculation results, it can be seen that the direct influence of store atmosphere on customer loyalty is 0.225 or 22.5%, greater than the indirect effect, which is 0.222 or 22.2%, which shows that if the value of direct influence > indirect effect, which means that indirectly store atmosphere has a significant effect on customer loyalty through customer satisfaction. However, because the value of the path coefficient of direct influence is greater, it can be concluded that the store atmosphere has a greater influence on customer loyalty than customer satisfaction.

Based on the results of path analysis and hypothesis testing that product quality has a significant positive effect on customer satisfaction at Alfamart Jember, so  $H_0$  was rejected and  $H_1$  accepted. Based on the results of the calculation of the direct influence of product quality on customer satisfaction, which is 24.2%, this means that the quality of the product provided is very good, despite the limitation of operating hours, but still does not reduce customer satisfaction shopping at Alfamart Jember. The results of this study support the research of Yulisetiari *et al.* (2018) states that product quality has a positive effect on customer satisfaction. Wirawan *et al.* (2019) state that product quality has a significant effect on customer satisfaction. This study supports Syahmi *et*

*al.* (2021) which states that product quality has a significant positive effect on customer satisfaction. The results of this study strengthen the theory that is consistent and proven product quality has an effect on customer satisfaction.

Based on the results of path analysis tests and hypothesis testing that store atmosphere has a significant positive effect on customer satisfaction at Alfamart Jember, so  $H_0$  was rejected and  $H_2$  accepted. Based on the results of the calculation of the direct influence of store atmosphere on customer satisfaction, which is 56.7%, this means store atmosphere that the available has made customers feel comfortable and happy to linger in the store, so it does not reduce customer satisfaction despite restrictions on operating hours. The results of this study are in line with and support the research conducted by Winarjo and Japarianto (2017), Kumala *et al.* (2020), Yulisetiari and Mawarni (2021) which state that store atmosphere has a significant effect on customer satisfaction. The results of this study strengthen the position of the theory that a consistent and proven store atmosphere has a significant effect on customer satisfaction.

Based on the results of the path analysis test and hypothesis testing that product quality has a significant positive effect on customer loyalty at Alfamart Jember, so  $H_0$  was rejected and  $H_3$  accepted. Based on the results of the calculation of the direct influence of product quality on customer loyalty, which is 29.6%, this means that the quality of the product provided is very good, despite the limitation of operating hours, but still does not reduce customer satisfaction shopping at Alfamart Jember, so that customers will become more satisfied. more loyal later. The results of this study are in line with the research conducted by Yulisetiari *et al.* (2017), Gunawan *et al.* (2019), and Wulandari *et al.* (2020) which shows that product quality has a positive effect on customer loyalty. The results of this study strengthen the position of the theory and can show consistency because it is proven that

product quality has a significant effect on customer loyalty.

Based on the results of path analysis tests and hypothesis testing that store atmosphere has a significant positive effect on customer loyalty at Alfamart Jember, so  $H_0$  was rejected and  $H_4$  accepted. Based on the results of the calculation of the direct influence of store atmosphere on customer loyalty, which is 22.5%, this means store atmosphere that a comfortable make customers enjoy the whole shopping process and feel at home in the store despite restrictions on operating hours, still making customers come back again in the future. The results of this study are in line with and support research conducted by Winarjo and Japariato (2017) showing that store atmosphere has a significant effect on customer loyalty. Subsequent research conducted by Gunawan *et al.* (2019); Yulisetiari and Mawarni (2021) stated that store atmosphere had a significant positive effect on customer loyalty. The results of this study strengthen the theoretical position and can show consistency because it is proven that store atmosphere has a significant effect on customer loyalty.

Based on the results of path analysis and hypothesis testing, customer satisfaction has a significant positive effect on customer loyalty at Alfamart Jember, so  $H_0$  was rejected and  $H_5$  accepted. used on the results of the calculation of the direct influence path of customer satisfaction on customer loyalty, which is 39.3%, this means that customers are satisfied, so that customers will enjoy the same product or service again and be loyal to the company despite limited operating hours. The results of this study are in line with and support the research conducted by Wardhana (2016), Wirawan *et al.* (2019), and Syahmi *et al.* (2021) which shows that customer satisfaction has a significant effect on customer loyalty. The results of this study

strengthen the theory and can show consistency because it is proven that customer satisfaction has a significant effect on customer loyalty.

### 4.3 Practical Implications

Based on the results of the analysis and discussion that have been described previously, it can be seen the practical implications in accordance with the benefits of the research are as follows.

#### a. For academics

This research can provide additional insight, knowledge and be used as reference material for further research related to product quality, store atmosphere, customer satisfaction, and customer loyalty.

#### b. For Alfamart

This research can be used as input for Alfamart Jember in determining strategies and what factors to continue to improve customer satisfaction so that it will also have an impact on customer loyalty.

### 4.4 Research Limitations

This research is in accordance with scientific procedures, but this research has limitations that are expected to be a reference material for further research to be better. The limitations of this study are as follows.

a. The data collection method in this study used a questionnaire distributed online through several social media, such as Instagram, Whatsapp, Facebook, Twitter, and telegram due to the Covid-19 pandemic which made face-to-face activities limited. Questionnaires distributed online also have limitations, such as respondents filling in the same answers, causing bias, incomplete answers from respondents because there was no assistance when filling out the

questionnaire so that there were some things that were not understood.

## 5. Conclusion

### 5.1 Conclusion

Product quality has a significant positive effect on customer satisfaction. The better the product quality which consists of performance, durability, features, reliability, aesthetics, and serviceability, the more customer satisfaction will also increase. Store atmosphere has a significant positive effect on customer satisfaction. The more comfortable the store atmosphere which consists of the marquee, parking facilities, sound, temperature, store personnel, cleanliness, classification of store offerings, and a straight traffic flow provided to customers, the customer satisfaction will also increase. Product quality has a significant positive effect on customer loyalty. The better the product quality which consists of performance, durability, features, reliability, aesthetics, and serviceability, the more customer loyalty will also increase. Store atmosphere has a significant positive effect on customer loyalty. The more comfortable the store atmosphere which consists of the marquee, parking facilities, sound, temperature, store personnel, cleanliness, classification of store offerings, and a straight traffic flow provided to customers, customer loyalty will also increase. Customer satisfaction has a significant positive effect on loyalty. customer. The higher the satisfaction felt by the customer, the more customer loyalty will increase. Product quality has a significant effect on customer loyalty through customer satisfaction. Store atmosphere has a significant effect on customer loyalty through customer satisfaction.

### 5.2 Suggestions

Based on the results of the tests that have been carried out, there are several suggestions that can be given, as follows.

- a. For Alfamart
  - 1) Product quality variable (X1) which is divided into 6 indicators at Alfamart Jember is already very good in the minds of customers. The statement item X1.1 has the highest mean value with indicators performance in it, this shows that respondents agree that customers feel that products private label Alfamart Jember Are ready to be used according to their functions. The statement item X1.4 has the lowest mean value with indicators reliability in it, this shows that respondents agree that customers feel that products private label sold at Alfamart Jember are in very good condition but still need to be improved.
  - 2) Variable store atmosphere (X2) which is divided into 8 indicators at Alfamart Jember is good and in accordance with the hearts of customers. The statement item X2.1 has the highest mean value with an indicator marquee in it, this shows that the respondents strongly agree that the shop signboard with the words "Alfamart" which is characterized by red color is very clear and easy to find by customers. The statement item X2.3 has the lowest mean value with an indicator sound in it, this shows that respondents agree that the music presented at Alfamart Jember is able to make customers not bored but still needs to be improved.
  - 3) The customer satisfaction variable (Z) which is divided into 3 indicators at Alfamart Jember has been very good in the hearts of customers. The statement item Z2 has the highest mean value with an indicator of ease of obtaining in it, this shows that respondents strongly agree that it is easy when shopping at Alfamart Jember. The statement item Z3 has the lowest mean value with indicators of customer feelings after using it, this shows

that respondents agree that customers are happy after making a purchase but still need to be improved.

- 4) Customer loyalty variable (Y) which is divided into 3 indicators at Alfamart Jember which is felt by customers is quite high. The statement item Y3 has the highest mean value with an indicator continue purchasing in it, this shows that respondents agree that customers will make repeat purchases at Alfamart Jember in the future. Statement items Y2 has the lowest mean value of the indicator recommending the company to someone who seeks advice in it, it shows the respondents strongly agree

that customers will recommend to shop in Jember Alfamart to those nearby but still needs to be improved.

b. For Academics

For further research, it is expected to use other analytical methods, such as structural equation modeling (SEM), partial least squares (PLS) and according to the results of the calculation of the coefficient of total determination, it is recommended to add other variables, such as brand image, price, service quality, promotion, sales, repurchase interest, and so on to customer satisfaction and customer loyalty at retail outlets.

## A STUDY ON FACTORS INFLUENCING THE CONSUMER BUYING BEHAVIOR WITH REFERENCE TO ORGANIZED APPAREL RETAIL OUTLETS

**Abstract:** *The Indian Retail sector has come off age and has gone through major transformation over the last decade with a noticeable shift towards organized retailing. Modern retail formats, such as hypermarkets, superstores, supermarkets, discount and convenience stores are widely present in the developed world, whereas such forms of retail outlets have only just begun to spread to developing countries in recent years in Bangalore. Organized retail provides consumers with a wider choice of products, lower prices, and a pleasant shopping environment. Store atmospherics plays an important role in choice of the stores. The objective of this study is to identify the store related factors that have an influence on the consumers' decision process. Structured questionnaires were administered for a sample size of 400 customers who visited the shopping mall. There are several dimensions in a retail store. Hence, PL-SEM model has been used and three factors have been identified from the factor loadings analysis. The three factors under different parameters are-External Cues, Atmospherics and Merchandise.*

**Keywords:** *Consumer behavior, Retail, Store atmospherics, merchandise*

### 1. Introduction

The retail garment market scenario in India has gained a strong position as the third most attractive apparel retail market after Brazil and China. The retail clothing market contributed to the second turnover of the retail trade in India.

The apparel retail market has managed to take advantage of modern management concepts that lead to a better product offer, better customer management and scientific techniques for managing the supply chain retail. Apparel is expected to continue and experience greater retail penetration outside major urban groups and increased demand for branded products.

Retail stores create their own image in the minds of customers that have an impact on the purchases and perception of the products they carry from the stores. They also have self-respect, firmly connected with their behaviour. The various elements of the store image have an effect on the result of the customers.

The rationale behind this study was to spot store image features, sector-specific and evaluate the power and significant effect of each attribute on buyer buying decision. It also examined the effect of a range of demographic variables, on the buyer's evaluation of the different dimensions of the store perception.

**Retail Industry Scenario In India:**

Retail industry has transformed in a span of a decade, from traditional Kirana store to new formats such as department stores, hypermarkets, speciality stores, and malls. Modern formats have proliferated in metros and subways.

With rapid growth in the retail sector in the Indian market where it has reached the maturity phase, it has paved a way for the organised retail sector. India has been ranked on the fourth position as the most attractive countries among the global markets. Retailing in India is still in nascent stage. Organized retail represented only 7% of the

overall retail market in 2011-2012, and would reach 10.2% of the total retail sector in 2021-2022.

Retail sector is alienated into organized and unorganized sectors. Unorganized retailing includes Kirana or Mom and Pop stores. These retailers do not follow the government taxation norms. Unorganized retail is stores administered by owners without technical and accounting standardization. Unorganised retail refers to the local kirana retailers, convenience stores, corner hardware stores, small pharmacies etc. It is a family run business. Retailers of these stores are not so qualified, lack experience and visibility.

**Table 1.** Classification of store image components

Component	Details
Price of merchandise	Low prices Competitive or non-competitive prices
Quality of merchandise	Good or poor quality of merchandise Stock brand names
Assortment of merchandise	Breadth and depth of assortment Carries or not the brand the customer wants Carries or not elegant brands
Sales personnel	Attitude of sales personnel Knowledge of sales personnel Number of sales personnel Good or poor service
Location convenience	Location from home/work Access Good or poor location
Other convenience factors	Parking Hours store is open Convenience with regard to other stores Store lay-out with respect to convenience Convenience in general
Services	Credit Delivery Ease of return Self-service
Sales promotions	Special sales Stamps and other promotions Displays Symbols and colors
Advertising	Style and quality of advertising Media and vehicle used Reliability of advertising
Store atmosphere	Lay-out of store without respect to convenience External and internal décor of store Congestion Prestige of store Congeniality
Institutional	Reputation for fairness Conservative or modern
Clientele	Social class Self-image
Physical aspects	Facilities Architecture Shopping ease

## 2. Literature Review

1) Tripathi and Sinha (2008) in their document proposes to link the choice of the store, the choice of format and the demographic variables of the consumer, through a hierarchical logistic choice model in which consumers first choose a format of store and then a private store within that format. Empirical analysis was used. The result of the study was the number of members in the family, income and employment hours that can be captured. In the short term (for example, one year), these variables can also be stable, and the temporal aspect of the model can be really ignored for these variables. The identified research gap was a better model

2) Raghava Rao Gundala (2010) identified the image attributes of the store and assessed the strength and impact of each attribute on the purchase decision. It also analyzes the influence of demographic variables and on the consumer's assessment. Analysis was done using ANOVA and F test and it was found that the t-values of the attributes were not significant at the values of 0.05 and 0.01. There was a significant correlation between the demographic variables and the various images attributes of the business. The findings assist retailers to know the impact of the store image and its relationship to store patronage in this volatile market.

3) Krishna C.V (2011) in his article addresses the determinants that affect consumer preferences for private brands. In this study it was found that four aspects, namely the image of the brand, promotion offers, design and the store exteriors and interiors affect consumer priority for private-level brands. In addition, the study revealed that demographic aspects the consumer's occupation and the social class of the consumer, have no effect on consumer purchasing behaviour when selecting private brands. The research gap focused only on

private brands.

4) Narang Ritu (2011), the research was carried in the Tier II city. It included Indian youth and his goal was to recognize the role of psychographic characteristics in the selection of clothing stores. The methods of data collection consisted of in-depth interviews and group discussions of young people and retailers.

Both categories were determined by the environment, design, layout and accessibility to the newest designs and styles in the selection of the clothing store.

5) Khanna, Kesharwani and Rajput (2012) the intention was to determine the problems related to the purchasing decision, based on the gender point of view. The aim was to assess the importance of demographic profile of customers who make the decision to buy the brand attire. The result indicated that, there is no significant difference in purchase costs, brand awareness and regularity of purchase between men and women.

6) Rome, Siochi and Plaza (2017) In his study, he evaluated the factors that influence the impulse of consumer purchase in the supermarket environment. Quota sampling was used because the total sample size was evenly distributed to obtain a specific sample size for each supermarket. The convenience sampling technique was also used when the sponsor was already at the study site. The four external factors (store environment, store navigation, provider focus and promotion) with a positive regression coefficient indicate that they were statistically significant predictors of the study dependent variable (impulse buying behaviour). This study focused on evaluating factors associated with demographic factors, store characteristics and situational factors. Therefore, this study recommends that there is a scope for the researchers in future on factors that influence in stimulating the purchase of the consumer.

### **3. Research Methodology**

#### **3.1. Statement of the problem**

Retail industry is emerging at a very faster pace and growing day by day. There is a heterogeneous group of customers in the city of Bangalore since it is a metropolitan city. As the population grows, customer expectations increase.

Retailers should know the tastes and preferences of the consumers, to maintain their competitive advantage. The characteristics of the consumer, various components of the retail store, the image of the store, the selection of the store are key areas and have a fundamental role in the success of the retail sale. The marketing mix associated with the components of the store image contribute to overall image of the store.

As a growing percentage of clothing buyers prefer retail stores in metropolitan areas and cities, most organized clothing retailers will grow. The sector witnesses the integration of new national and international actors. However, clothing retailers face many challenges when they create new points of sale: location, store format, price, marketing, personnel, etc. These decisions entail huge predetermined costs that hinder the recovery of the investment if an error occurs in the location or format of the store. Customers expect maximum benefit for the price they pay. It is challenging to identify the factors that would attract and also retain the customers. Hence, marketers should be aware of the factors which influence the buying decision process while shopping at organized outlets.

Since very less research has been done on the attributes of the store image and the consumer's purchasing behaviour. Therefore, this study seeks to collect data about the research question If relationship exists between the attributes of the store's image

and the consumer's decision-making process.

#### **3.2. Objectives of study**

1. To explore the factors that influence the buying behavior of consumers while shopping of apparels in organized retail outlets,
2. To study the relationship between a stores' image and a consumer Satisfaction

#### **3.3. Scope of the study**

Proposed study is intended in order to take into account the attributes that influence consumer purchasing behaviour in organized retail apparel stores.

This study tried to discover and evaluate the relationship between store attributes and purchasing behaviour at the Shopping Malls Bangalore. It was important to assess the true drivers of shopping activities of the buyers. It also inspected the effect of a range of demographic variables like gender age and income on buyer,s assessment of different store image attributes. The present scope of the study was confined to organised clothing retail outlets.

### **4. Research design**

1. Descriptive research design has been used in this study. It involves studying the consumer characteristics. A descriptive research methodology was adopted because the objective of the study was to provide a systematic & factual description of the store image dimensions having an influence on their purchase decisions.
  2. Sources of Data Collection
    - i) Primary data: Primary data for this study has been gathered through the survey method.

The primary data was collected from the major apparel retail outlets in Bangalore, where respondents were customers who have finished their shopping in the store and ready to answer to the queries using the structured questionnaire.

ii)Secondary Data

Secondary data was composed from several consultancy and research organizations that on a regular basis develop and generate periodic reports on the retail sector in India, such as the retail details ICRIER, RNCOS, AT Kearney, BMI India Retail Report, Technopak, RAI, CII . Internet has been used to obtain relevant information for the study. The online libraries of Google, Google scholar, Ebsco, Springer and J-gate were also used to obtain relevant documentation for this purpose. Several books on market research, retail sales management, marketing management and consumer behaviour and professional journals were also used to obtain relevant information for the survey.

Sampling technique

The sample size corresponding to a population of 20,000 is 377 and for the population of 10, 00,000 it is 384. Based on sq.ft and zone wise stratified random sample is used, the given below table showed the sample proportion drawn.

HYPOTHESIS:

- $H_{a1}$ : There is relationship existing between Retail store and Overall Satisfaction of retailers consumers.
- $H_{a2}$ : The relation between Retail store and Overall satisfaction is higher for the retailers who opted to purchase decision while compared to retailers who does not opt

## 5. Data analysis and interpretation

Impact of Product and Store Attributes on the consumer purchase decisions at the retail

stores.

### 1. Product and Store based attributes

**Table 2.** Product and Store based Attributes

Product and Store based Attributes	Frequency	Percentage
Apparel factor Brand	167	41.75
Celebrity	10	2.50
Color	109	27.25
Design	83	20.75
Visual	31	7.75
Product Sensitivity Fabrication	203	50.75
Peer appreciation	32	8.00
Price	48	12.00
Social value	55	13.75
Touch	62	15.50
Apparel attribute Accessories	58	14.50
Brand Image	135	33.75
Newness	164	41.00
Style	43	10.75
Apparel type Celebrity Endorsed	113	28.25
Long Fashion Life Cycle	116	29.00
Premium Quality	30	7.50
Public Image Driving	141	35.25
Personalized apparel No	161	40.25
Yes	239	59.75
Factor of Store Brand to buy Customer Services	19	4.75
Personalization	111	27.75
Price	118	29.50
Store Image	152	38.00

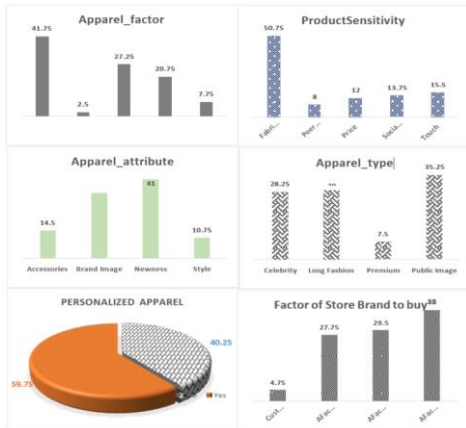

Figure 1. Product and Store based Attributes

With reference to Product and Store based Attributes,

A) Apparel factor

Brand attained maximum response of 41.75%, Colour attained response of 27.25%, Design attained response of 20.75%, Visuals attained response of 7.75% while Celebrity attained the minimum response of 2.50%. From the analysis, it implies that majority of the customers are more concerned with the brand when they are purchasing from the stores.

1. Product Sensitivity

Fabric attained maximum response of 50.75%, Price attained the response of 12%, Social value attained the response of 13.75%, Touch attained the response of 15.50% while Peer appreciation attained the minimum response of 8.00%. Thus, it reveals that quality of fabric of the apparel is an important aspect that has an influence on the buying behaviour.

2. Apparel attribute

Newness attained maximum response of 41%, Accessories attained the response of 14.50%, Brand Image attained the response of 33.75%, while Style attained the minimum response of 10.75%. Hence from the analysis of table 4.2.1 says that newness

of the apparel is the attractive factor that influences the customers to buy.

3. Apparel type

Public Image Driving attained maximum response of 35.25%, Celebrity Endorsed attained the response of 28.25%, Long Fashion Life Cycle attained the response of 29%, while Premium Quality attained the minimum response of 7.50%. Hence, public image is the major factor in the apparel type that has an influence on the purchases.

4. Personalized apparel

Majority 59.75% were yes while 40.25% of respondents were No.

5. Factor of Store Brand to buy

Store Image attained maximum response of 38%, Price attained the response of 29.50%, Personalization attained the response of 27.75% while Customer Services attained the minimum response of 4.75%. Image of the store is the one of the reason for consumers to buy at the stores.

Objective1 To explore the factors that influence the buying behavior of consumers while shopping of apparels in organized retail outlets.

EFA recognizes primary factor structure identifying the purchasing factors of Retail stores attributes.

Factors identified are named as External Cues, Store Atmospheric and Merchandise.

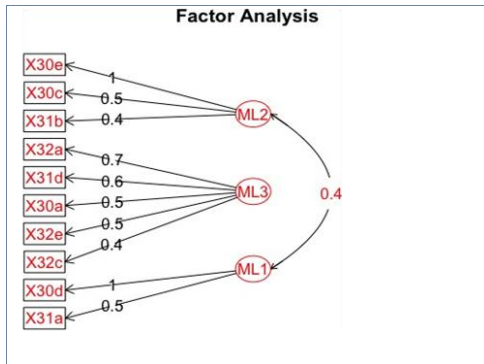

Figure 2. Store dimension factors extracted

The above graph depicted the Eigen value in Y axis, number of factors in X axis. Based on Eigen value is more than 1, number of factors determined is 3. The three factors identified are External cues, Atmospherics, and Merchandise.

**Figure 3.** Factor loadings to indicate the relation between atmospherics and Merchandise

The above Graph no. 4.42 showed that 3 factors with factor loadings, between Store Atmospherics (ML2) and Merchandise (ML1) the relation is .40. which indicate that the variance is less between the factors and there is an association between the two. Since there is an association between the two they can be considered for the study.

## 6. Summary of findings, suggestions & conclusions

The hypotheses framed are to test the association between demographic factors and consumer purchase decisions. To explore the relationship between store image dimensions, store atmospherics on the consumer purchase decisions.

**Table 3.**

Objectives of the study	Variables Used	Research Hypothesis	Statistica Techniques	Outcome of the Analysis
Objective 1 To explore the factors that influence the buying behavior of consumers while shopping of apparels in organized retail outlets	16 items [X30a through X32e] [Refer Descriptive stats]	Since model is exploratory, hypothesis is not required	Exploratory factor analysis Eigen > 1, KMO > .5, Estimation: ML Factor loadings > .4 Rotation: Oblimin	3 factor derived, factors names as External Cue, Atmospherics, and Merchandise. Total variance explained close to 50% [ 10 items are retained for further analysis]
			Descriptive statistics and graphs	Describing the dimension response
			Reliability test Cronbach alpha is more than .7 dimension wise	

2. The study reveals that, with reference to Product and store based attributes, in apparel factor brand is the most preferred attribute with a highest response of 41.75% followed by other attributes like colour, design, visual and the influence of celebrity endorsements.

- Also, the other attributes like fabrication was the most preferred attribute in product sensitivity with a response of 41.75%. Similarity in

the apparel attribute newness of the merchandise at the store attained a highest response with 41%.

- Public Image driving was the driving force for purchase which attained a highest response of 35.25% as compared to celebrity endorsements, long fashion life cycle and premium quality.
- Majority of respondents i.e.59.75% customers agree that they would like to purchase personalised apparels
- It was found from the study that, store image is the major factor which motivates respondents to shop only at particular branded apparel stores.

Suggestions:

- 1) Physical aspects and Store atmospherics were rated as vital predictor of store choice. The effect was more than all the other relationships explored. It suggests the interior of store must be clean, structured and well maintained.
- 2) In addition, the design should be optimized to maximize convenience to customers. Aesthetic factors must be enhanced by the retailers to ensure marketers exceed customer expectations and retain them.

## 7. Conclusion

Physical aspects were the main forecaster of store choice. This underlines the notion that

## References:

- Ahmed, A. & Mujeeb, M. (2017). Indian Journal of Commerce & Management Studies, 8(1), January 2017, ISSN: 2249-0310 EI SSN: 2229-5674.
- AT Kearney. (2012, June 11). Global retail expansion: Keeps on moving.

the physical environment of store must be hygienic, well-structured and maintained. The customers prefer shopping in a store which is considered safe and healthy. Looking at changing behavioural occurrence retailers need to adapt themselves to the changing demands of the customers. Hence, it is important to understand the overall customer views regarding store image that influence customer store choice, purchase intention, store satisfaction and loyalty toward their ideal store. The store choice behaviour strongly influenced by location, convenience, store environments and reasonable price, merchandizing and sales assistance. Likewise, studies showed that purchase intention is stimulated by store image attributes like pleasant store environment and atmospheric indications, product variety and quality and price. However, complimentary store images make the customers revisit the store by augmenting store satisfaction. They can offer good service like people greeter at the entrances, checkout facilities by minimising queue hassles. Keeping this reality in mind, today's retailers are offering newer service dimensions to create unique shopping experiences for the customers. In the face of the increasing retail competition the marketing approach should assess consumer perception of store image for formulating effective marketing strategies to create and enhance appealing store image to influence the overall behavioural pattern of the customers".

## THE EFFECT OF COMPANY SIZE AND CORPORATE GOVERNANCE MECHANISMS ON PROFIT MANAGEMENT ACTIVITIES IN INDUSTRY 4.0

**Abstract:** *The purpose of the research is to examine whether firm size, managerial ownership, institutional ownership, independent board of commissioners, and audit committee have an effect on earnings management. The population in this study is coal sub-sector mining companies listed on the Indonesia Stock Exchange for the 2019-2021 periods. The data used is secondary data. The data collection method used is the method of literature study and documentation. The analysis used is multiple regression analysis. The results showed that: 1) the size of the partial variables had no effect and had no significant effect on earnings management; 2) partial managerial ownership, institutional ownership and significant effect on Earnings Management in a positive direction; 3) the partial variable of the audit committee has no effect on Earnings Management.*

**Keywords:** *Good Corporate Governance, Size Of Company, Earnings Management.*

### 1. Introduction

Financial statements are a summary of the process of recording financial transactions that occurred during one financial year. Financial reporting becomes a medium where companies provide financial information, as a management responsibility, to meet the needs of external parties, namely to obtain information about company performance (Warren et al., 2017).

According to Statement of Financial Accounting Concept (SFAC) No. 1, profit information is a measure of the performance of management's responsibility in achieving predetermined business goals and helps owners estimate the future profitability of the company (Putro, 2016). Profit information is often the goal of engineering through the opportunistic behavior of

management to maximize its satisfaction (Arizal et al., 2021). Self-serving behavior (speculation) is through the selection of certain accounting policies, so that profits can be adjusted, increased or decreased according to one's own wishes (Fadilurrahman et al., 2021). Profit management according to its own wishes is called profit management is the result of agency problems arising from the misalignment of interests between shareholders (principal) and company management (agent) (Habibah et al., 2021). The relationship between the principal and the agent can be asymmetrical information, because within the company the agent has more information than the principal, so the agent can hide the information for his own benefit. Asymmetry between management (agent) and shareholders (principal) provides

an opportunity for managers to obtain personal profit opportunistically (Handayani et al., 2022), and in financial reporting, managers can mislead owners through the view of profit management (shareholders) towards the economy of the company. (Karina & Sutarti 2021). Therefore, profit management is actually a tool for managers to realize personal wills and desires (Hidayat et al., 2021). While financial statements are a medium for managers to express their will and desire (Sulistiyanto, 2018; Surti et al., 2022).

One of the profit management phenomena is the case that occurred at PT Garuda Indonesia (Persero) Tbk. According to Nuroniyah (2020) It was reported in the financial statements that PT Garuda Indonesia (Persero) Tbk in 2018 experienced a profit by scoring a net profit of US\$ 809.4 thousand. This is surprising because PT Garuda Indonesia (Persero) Tbk should have suffered a loss. In recent years, the company has continued to suffer losses, throughout the first nine months of 2018 the company recorded a loss of US\$ 114.08 million (Irpan et al., 2021). The loss decreased compared to 2017 of US\$ 222.03 million. However, surprisingly at the end of 2018 PT Garuda Indonesia (Persero) Tbk reported that it experienced gains instead of losses (Iyansyah et al., 2021). This made two commissioners of PT Garuda Indonesia (Persero) Tbk, namely Chairul Tanjung and Dony Oskaria, unwilling to sign Garuda's 2018 yearbook report (Joko et al., 2022). Therefore, one of the ways that can be done to monitor these problems is to implement corporate governance in the company (Kurniawan et al., 2021; Shaddiq et al., 2021).

Based on several financial reporting scandals, the effectiveness of the implementation of good corporate governance (GCG) in companies is questioned to minimize profit management (Bintara 2019). Good Corporate

Governance (GCG) is a system of controlling and regulating the company which can be seen from the relationship mechanism between various parties that manage the company (hard definition), as well as in terms of the "values" that contained from the management mechanism itself (soft definition) (Norrahmi et al., 2021). Based on the previous research above, there is a GAP from the research results, therefore researchers are interested in conducting further research, where this research is replication of the Bintara research (2019). The difference between Bintara (2019) research and this research lies in the object, where the previous research object lies in metal sub-sector manufacturing companies and the like, while this research lies in coal sub-sector mining companies. This study investigates the practice of profit management practices and retests the factors that influence them such as ownership concentration, company size, corporate governance mechanisms and audit committees (Wijaya et al., 2021; Norrahmiati et al., 2022).

## **2. Literature review and hypothesis development**

### **Agency Theory**

According to Hendrawaty (2017) Agency theory explains that agency relationships occur when principals hire other people (agents) to provide services and then delegate decision-making power to agents. So that agents can manipulate company reports to principals because each manager has great financial needs, including maximizing his compensation by implementing profit management (Putera et al., 2022).

### **Financial Statements**

According to Cashmere (2013) financial statements are reports that show the current or future financial condition of the company.

The purpose and objectives of the financial statements indicate the financial position of the company.

### Profit Management

According to Abbas et al. (2019) profit management is an accounting policy or specific action chosen by managers to influence the rate of increase or decrease in reported profits and losses to achieve desired goals. As the manager of the company, the management knows the real state of the company better than the shareholders.

### Company Size

Oktaviana et al. (2020) suggest that the size of the company is a scale where it can be classified as the size of the company measured by total assets, number of sales, value of shares and so on, while according to Novianty and May (2018) the size of the company is seen from the field of business being operated.

### Corporate Governance Mechanism

Corporate governance is a tool that is considered to be able to solve problems in managing and controlling the company (Ramadhani et al., 2021).

### Effect of Company Size on Profit Management

Prasetya (2016) found that company size has a negative impact on profit management. Large companies have fewer incentives for profit management than small companies, meaning that the larger the company's income the smaller the amount of profit management.

### The Effect of Managerial Ownership on Profit Management

According to Manossoh (2016), the practice of profit management can align the differences in interests between owners and management by increasing the company's share ownership by management

(managerial ownership).

### The Effect of Institutional Ownership on Profit Management

Institutional ownership has the ability to control management through an effective monitoring process, thereby reducing profit management (Rizal et al., 2020). Institutions that have a certain percentage of shares will affect the process of preparing financial statements, but do not rule out the possibility of accruals for the benefit of management (Rito & Azzahra, 2018).

### The Effect of the Audit Committee on Profit Management

Effendi (2016) the audit committee can influence the profit management practices that occur in the company. The audit committee at the enterprise may reduce the practice of profit management that is the result of opportunistic actions carried out by managers (Saputra et al., 2020).

### Research Models

From the background, literature review, and previous research, the following research model is stated.

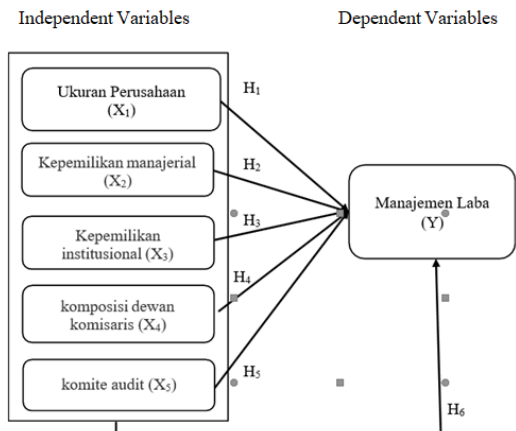

Figure 2.1 Research Model

### Hypothesis

Based on the framework of thought and research model discussed above, the hypothesis can be formulated as follows:

H1 : Company size affects Profit Management

H2 : Managerial ownership affects Profit Management

H3 : Institutional Ownership affects Profit Management

H4 : The composition of the Board of Commissioners affects Profit Management

H5 : Audit Committee affects Profit Management

H6 : Company Size, Managerial Ownership, Institutional Ownership, Composition of the Board of Commissioners of the Audit Committee simultaneously affect Profit

Management

### 3. Research methods

#### Population

This research is a quantitative study. The research focuses on secondary data, namely data obtained from annual reports. The population used in this study is all coal sub-sector mining companies listed on the Indonesia Stock Exchange (IDX) in 2019-2021, totaling 26 companies.

#### Sample

Based on the purposive sampling method, 13 companies were sampled in this study, with a total of 39 data. Details of the sample decline can be seen in the following table:

**Table 1.** Research Sample Criteria

No.	Sample Criteria	Total Samples
1	Mining Companies listed on the IDX for the period 2019-2021	29
2	Mining Companies that do not publish annual reports and complete research data for the period 2019-2021	3
3		13
4	<b>Total Data:</b> 13 × 3 years	39

Source: Processed Data (2022)

### Devinition of Research Variables

#### Profit Management (Y)

Profit management is the process by which management intervenes in the preparation of reports financial for external parties to balance, increase and reduce the condition of profit reporting. Profit management is measured using discretionary accruals (DACs). In this study, discretionary accruals were used as proxies because they are components that can be manipulated by managers such as credit sales. To measure the DAC, we will first measure the total accrual. Profit management (DAC) can be measured by discretionary accruals, which are calculated by differentiating between total accruals (TACs) and non-discretionary accruals (NDAs).

#### Company Size (X1)

The size of the company is measured by the total assets owned by the sample company, because the total assets reflect the size of the company, and the larger the assets owned by the company, the larger the company will be. Due to the high dispersion of total assets, natural logarithms are used to anticipate them (Sudiby, 2013).

#### Managerial Ownership (X2)

Managerial ownership is measured by the proportion of equity held by managers, directors, commissioners, and other parties actively involved in company decision-making, a variable used to determine the benefits of managerial ownership in reducing agency conflicts (Mutiasari, 2018).

### **Institutional Ownership (X3)**

Abdillah et al., (2015) state that institutional ownership is a percentage of the voting rights owned by the institution. The institutions referred to in this case include NGOs, governments and private companies. Higher institutional ownership will lead to tighter restrictions on managers' actions, thus hindering management's tendency to use discretionary accruals in financial statements.

### **Composition of independent Board of Commissioners (X4)**

Independent Commissioner is a member of the board of commissioners who has no financial, management, equity or family relationship or good relationship with other members of the board of commissioners, directors or controlling shareholders that may affect his ability to act independently. Non-executive directors (independent commissioners) may act as mediators in disputes between internal managers, oversee management policy and advise management. The greater the proportion of independent commissioners, the more it can reduce profit management practices (Abdillah et al., 2015).

### **Audit Committee**

The Audit Committee (AC) consists of at least 3 members, one of whom is an independent commissioner of a listed company who also serves as the chairman of the committee, and the other is an independent outsider, at least one of whom is competent in accounting and finance. The composition of the audit committee is measured using the indicator of the percentage of audit committee members from outside to all members of the audit committee (Fanani et al., 2020).

### **Data Retrieval Techniques**

The data collection technique used in this study was to use secondary data. The secondary data necessary for the study were

obtained by the method of documentation.

### **Data Analysis Techniques**

The data analysis method used in this study is multiple linear regression analysis. The tests carried out are descriptive statistical tests, normality tests, classical assumption tests, multiple regression analysis and hypothesis tests. The method of data analysis will be carried out with the help of the computer application program SPSS 26.

### **Hypothesis Testing**

#### *Partial Test (Statistical Test t)*

According to Ghozali (2013:98) the partial regression test (t) serves to find out whether the independent variable regression model partially has a significant effect on the dependent variable. Partial regression test (t) seen from the "Coefficient" table with a significance tolerance of 5%.

#### *Coefficient of Determination (R<sup>2</sup>)*

The Coefficient of Determination (R<sup>2</sup>) essentially measures how far the model is capable of explaining the variation of independent variables. The value of the coefficient of determination is between zero (0) and one (1). A small value (R<sup>2</sup>) means that the ability of independent variables to describe the variation of dependent variables is very limited. A value close to one (1) means that independent variables provide almost all the information needed to predict the variation of dependent variables (Ghozali, 2013:97).

## **4. Results of research and discussion**

### **Descriptive Statistical Analysis**

Descriptive statistical tests aim to provide an overview or description of a data that is visible from the number of samples, minimum values, maximum values, mean, and standard deviation of each variable. The following describes the statistics of the research data.

**Table 4.1** Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
UP	39	27.28	34.59	30.2190	1.77857
KM	39	0.00	0.12	0.0183	0.03439
KI	39	0.44	0.97	0.7813	0.15902
DKI	39	0.20	0.67	0.3836	0.09303
KA	39	3.00	5.00	3.2308	0.53614
ML	39	-0.30	2.25	0.7513	0.66537
Valid N (listwise)	39				

Source: Processed secondary data, 2022

**Multiple Linear Regression Test**

The testing of this study with multiple linear regression analysis aims to determine the influence of company size and corporate governance mechanisms on profit management activities in coal sub-sector

companies for the 2019-2021 period. Previously this model had already met the normality test and the classical assumption test. The following are the results of multiple linear regression analysis presented in the next table.

**Table 4.2** Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	0.014	1.783		0.008	0.994
	UP	-0.017	0.055	-0.046	-0.308	0.760
	KM	8.565	3.086	0.443	2.776	0.009
	KI	2.159	0.658	0.516	3.280	0.002
	DKI	-3.416	1.067	-0.478	-3.201	0.003
	KA	0.222	0.173	0.179	1.286	0.207

a. Dependent Variable: ML

Based on Table 4.2 to form a multiple linear regression equation can be seen in the Unstandardized Coefficient table of column B (Beta) which is 0.014 for constant values, -0.017 for company size values, 8.565 for managerial ownership, 2.159 for institutional ownership, -3.416 for independent boards, and 0.222 for audit committees. Therefore, from these values, a multiple linear regression equation can be formed as follows.

$$Y = 0.014 - 0.017X_1 + 8.565X_2 + 2.159X_3 - 3.416X_4 + 0.222X_5 + e$$

**Simultaneous Significance Test (statistical test F)**

Based on the table 4.3, it can be seen that the significant value is  $0.004 < 0.05$  (significance level) with a calculated F value of  $4.325 > F$  table 2.50. This shows that the variables of company size, managerial ownership, institutional ownership, independent board of commissioners, and audit committee simultaneously have a significant effect on profit management.

**Table 4.3 ANOVA**

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	6.660	5	1.332	4.325	0.004 <sup>b</sup>
	Residual	10.163	33	0.308		
	Total	16.823	38			

a. Dependent Variable: ML

b. Predictors: (Constant), KA, DKI, KM, UP, KI

Source: Secondary data processed, 2022

### Discussion of Research Results

Based on hypothesis testing carried out both partially and simultaneously on the measurement of company size, the corporate governance mechanism for profit management activities can be explained as follows.

#### Effect of Company Size on Profit Management

The company size variable has a t-count of -0.308 and a t-table value of 2.034. Then the t-count value < t-table, which is  $-0.308 < 2.034$  with a significant value of  $0.760 > 0.05$ . It can be concluded that H1 is rejected meaning that the size of the company has no effect on profit management. The results of this study are not in accordance with Santi & Wardani, (2018) who argue that company size has a negative and significant effect on profit management. However, the results of this study are in accordance with the research of non-commissioned officers, (2019) which argues that the size of the company has no influence on profit management. This is because large companies have more assets and allow many assets that are not managed properly so that there is a possibility of errors in disclosing the total assets in the company.

#### The Effect of Managerial Ownership on Profit Management

The managerial ownership variable has a t-count value of 2.776 and a t-table value of 2.034. Then the calculated value > t-table, which is  $2.776 > 2.034$  with a significant

value of  $0.009 < 0.05$ . It can be concluded that H2 is accepted meaning that managerial ownership affects profit management. It can be interpreted that the existence of managerial ownership in coal sub-sector mining companies listed on the Indonesia Stock Exchange (IDX) for the 2019-2021 period has an influence on profit management activities. The results of this study are in accordance with Lestari et al. (2016) and Purwanti et al. (2021). That is, the greater the concentrated shareholding, the more shareholders can be in a strong position to effectively control management so as to be able to limit oportunis behavior by managers.

#### The Effect of Institutional Ownership on Profit Management

The institutional ownership variable has a t-count value of 3,280 and a t-table value of 2,034. Then the t-count value > t-table, which is  $3,280 > 2034$  with a significant value of  $0.002 < 0.05$ , then H3 is accepted meaning that institutional ownership has a positive and significant effect on profit management. It can be interpreted that the higher the number of institutional ownership shares, the lower the profit management action. The results of this study are in accordance with research conducted by L. Mamu & Eka Damayanthi, (2018) and Bintara, (2019). These institutional investors have the opportunity, resources and ability to monitor, adjust, and influence managers in terms of management opportunistic practices. This makes managers feel

burdened to adjust the profit targets that institutional investors want and as a result there is a tendency to profit management practices to satisfy institutional parties. This makes the manager's reason for short-term profit management practices, because the institution is a temporary shareholder and only focuses on short-term profit.

#### **Effect of Independent Board of Commissioners on Profit Management**

The independent board of commissioners variable has a t-count value of - 3.201 and a t-table value of 2.034. Then the value of t-count > t-table, which is  $-3.201 > 2.034$  with a significant value of  $0.003 < 0.05$ , therefore H4 is accepted meaning that the independent board of commissioners affects profit management. This shows that the number of independent boards of commissioners in coal sub-sector mining companies listed on the Indonesia Stock Exchange (IDX) for the 2019-2021 period in carrying out supervisory functions, independent commissioners can also supervise management policies in the preparation of financial statements, so the financial reporting supervision process carried out by the board of commissioners will be more effective so as to prevent profit management practices. The results of this study are in accordance with research conducted by Purwanti et al., (2021) which argues that an independent board of commissioners affects profit management.

#### **Effect of Audit Committee on Profit Management**

The audit committee variable has a calculation of 1.286 and a t-table value of 2.034. Then the t-count value < t-table, which is  $1.286 < 2.034$  with a significant value of  $0.207 > 0.05$ . It can be concluded that H5 is rejected, meaning that the size of the company has no effect on profit management. The results of this study state that the proportion of the number of audit

committees in coal sub-sector mining companies listed on the Indonesia Stock Exchange (IDX) for the 2019-2021 period has not been able to reduce profit management carried out by management in a company. This is allegedly caused because the appointment of the audit committee by the company is only carried out for regulatory compliance but not intended to uphold good corporate governance in the company.

#### **Effect of Company Size, Managerial Ownership, Institutional Ownership, Independent Board of Commissioners, and Audit Committee on Profit Management**

Variable company size, managerial ownership, institutional ownership, composition of the board of commissioners of the audit committee has an F-count of 4,325 and an F-table value of 2.50. Then the F-value is calculated > F-table, which is  $4.325 > 2.50$  with a significant value of  $0.004 < 0.05$ . Judging from the Adjusted R Square value of 0.304, it shows that it is 30.4%. It can be concluded that H6 is accepted meaning that the size of the company, managerial ownership, institutional ownership, the composition of the board of commissioners of the audit committee have a simultaneous effect on profit management. It can be interpreted that the size of the company, managerial ownership, institutional ownership, the composition of the board of commissioners of the audit committee in coal sub-sector mining companies listed on the Indonesia Stock Exchange (IDX) for the 2019-2021 period have a simultaneous influence on profit management activities. The results of this study are in line with Bintara, (2019) which states that together profit management is influenced by company size, managerial ownership, institutional ownership, composition of the board of commissioners of the audit committee.

## Coeffesient Determination Test

Based on the table 4.4, it can be seen that the Adjusted R Square value of 0.304 shows that 30.4% of the dependent variables, namely profit management, can be explained

by independent variables, namely company size, managerial ownership, institutional ownership, independent board of commissioners, and audit committees. While the remaining 69.6% is explained by other variables outside the regression model.

**Table 4.4** Model summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.629 <sup>a</sup>	0.396	0.304	0.55496

a. Predictors: (Constant), KA, DKI, KM, UP, KI

b. Dependent Variable: ML

Source: Secondary data processed, 2022

## 5. Conclusion

The results of simultaneous testing are known that there is a significant influence of independent variables on dependent variables, namely company size, managerial ownership, institutional ownership, independent board of commissioners and audit committees together it has a significant effect on profit management.

The results of partial testing with t-test show that managerial ownership, institutional ownership, and an independent Board of Commissioners have a significant effect on profit management, while the audit committee and company size have no significant effect on profit management.

This section presents research conclusions, research limitations, and suggestions for subsequent research. The Conclusion section is written in one chapter and there are no subtitles.

## ON THE RELATION BETWEEN ENTREPRENEURSHIP AND QUALITY MANAGEMENT

**Abstract:** *Healthy business ecosystems are necessary for competitive advantage, the major force of the trade economy, and free markets. Business sustainability requires entrepreneurship skills, knowledge, and competencies, as well as standardization of processes, procedures, etc., which relate to quality management patterns. Entrepreneurship can be measured, and so can quality management. Most international, regional, and local business organizations, individual businesses, as well as several researchers, assert that there is a connection between entrepreneurship and quality management, especially with ISO standards.*

*Therefore, it is necessary to research the relations between entrepreneurship and quality management to provide a clear insight into the issue. This study is based on a regression analysis between the Entrepreneurship Index (E Index) and ISO Standards Index to verify Hypothesis H1 (There is not any relation between E Index and ISO Standards Index) against Hypothesis H0 (There is a strong relation between E Index and ISO Standards Index). The results of the research show that entrepreneurship requires scientific management of factors of production, employing skills, knowledge, and competencies, as well as using quality management principles, to achieve a competitive advantage, so, a connection and relations between entrepreneurship and quality management (ISO standards), is indispensable. It can be stated from the conducted research that there is no relation between entrepreneurship and ISO standards yet, even though it is highly needed and should exist to promote sustainable entrepreneurship with no support at all.*

**Keywords:** *Entrepreneurship, business sustainability, competitive advantage, quality management, ISO standards, ISO standards Index*

### 1. Introduction

In this critical analysis, relations between entrepreneurship and International Standards of quality management are investigated, as they are important factors in healthy business ecosystems.

There is supposed to be a strong relationship between entrepreneurship and quality management principles, especially with ISO

standards, considering that disruption and uncertainty continue in multiple business sectors; but, as most entrepreneurs know well, with disruption comes opportunity and it is clear that entrepreneurs have been grasping pandemic-related opportunities and building resilience while living with the pandemic has certainly raised awareness of the business opportunities it brings in its wake (GEM (Global Entrepreneurship

---

Email: [enrikoceko@yahoo.co.uk](mailto:enrikoceko@yahoo.co.uk)

Monitor) (2022)).

This was the core issue to be investigated in this research, using quantitative methods, combined with a regression analysis on relations between the Entrepreneurship Index and ISO standards Index.

Also, there were have taken into account other sources to have thorough research such as classified existing data and materials about entrepreneurship, quality management, and ISO standards, the updated ones together with the previously published works and scholarly articles books, as well as online libraries.

There are strong and sustained relations between quality management / ISO standards and the climate of doing business (Ceko, 2016a). There are strong and sustained relations between the climate of doing business and life quality, which is already verified scientifically (Ceko, 2016b). Improving quality management systems / respecting ISO standards parallel with doing business regulations / doing business climate, can improve the life quality of citizens.

Worldwide countries recently are facing problems that affect the development and performance of businesses, entrepreneurship activity, development and economic growth, sustainable development, and life quality.

Establishing quality institutions, quality infrastructure, and doing business worldwide, using ISO standards, will have a positive impact on entrepreneurship activities and doing business as it leads to increasing economic growth and improving the quality of life of citizens in a wider perspective, as a part of long-term sustainable development.

## 2. Material and Methods

### 2.1. Entrepreneurship

Entrepreneurship is the creation or extraction

of economic value (Diochon et al., 2011; Gaddefors et al., 2017; Alvarez, and Busenitz, 2001). With this definition, entrepreneurship is viewed as change, generally entailing risk beyond what is normally encountered in starting a business, which may include other values than simply economic ones.

An entrepreneur is an individual who creates and/or invests in one or more businesses, bearing most of the risks and enjoying most of the rewards. The process of setting up a business is known as entrepreneurship. The entrepreneur is commonly seen as an innovator, a source of new ideas, goods, services, and business/or procedures. In the field of economics, the term entrepreneur is used for an entity that can translate inventions or technologies into products and services. In this sense, entrepreneurship describes activities on the part of both established firms and new businesses.

As an academic field, entrepreneurship accommodates different schools of thought. It has been studied within disciplines such as management, economics, sociology, and economic history (Lindgren, et al., 2009; Neergaard et al., 2007).

Entrepreneurship is the act of being an entrepreneur, or the owner or manager of a business enterprise who, by risk and initiative, attempts to make profits. Entrepreneurs act as managers and oversee the launch and growth of an enterprise. Entrepreneurship is the process by which either an individual or a team identifies a business opportunity and acquires and deploys the necessary resources required for its exploitation.

Regardless of the firm size, big or small, they can take part in entrepreneurship opportunities. The opportunity to become an entrepreneur requires four criteria. First, there must be opportunities or situations to recombine resources to generate profit. Second, entrepreneurship requires

differences between people, such as preferential access to certain individuals or the ability to recognize information about opportunities. Third, taking on risks is a necessity. Fourth, the entrepreneurial process requires the organization of people and resources (Shane, 2009).

The entrepreneur uses their time, energy, and resources into creating value for others. They are rewarded for this effort monetarily and therefore both the consumer of the value created and the entrepreneur benefit.

Strategies that entrepreneurs may use include:

- 1) Innovation of new products, services, or processes
- 2) Listen to customer feedback and adapt
- 3) Continuous process improvement (CPI)
- 4) Exploration of new business models
- 5) Finding solutions for problems
- 6) Use of technology
- 7) Use of business intelligence
- 8) Use of economic strategies
- 9) Development of future products and services
- 10) Optimized talent management
- 11) Entrepreneurial marketing strategies for interactive and innovative networking (Qureshi, 2015; Adel et al., 2020).

These strategies are part of the quality management subject too (Ceko and Mecalla, 2017).

For the period of pandemics and post-pandemics, several entrepreneurship challenges have been identified (GEM Report), including that in some countries one in two adults agreed their household income had decreased, comparing 2021 to 2019 (pre-pandemic), Total Early-stage Entrepreneurial Activity (TEA; GEM's most well-known indicator, representing the percentage of adults that are starting or running a new business) has typically decreased and this

has also been the case for levels of Established Business Ownership (EBO; the percentage of adults aged 18–64 owning or managing a business for more than 42 months), in a quarter of the GEM economies, over half of those starting or running a new business expect to employ no one but themselves in five years. This may be indicative of high levels of informal “survival” businesses, created during economic hardship when no other alternatives or social safety nets are available, and when people resort to entrepreneurship as their only fallback solution. Consistent with crises throughout history, the COVID-19 pandemic crisis surfaced new opportunities for entrepreneurs around the globe, however, despite positive perceptions of the ease of starting a business, self-confidence in their skills and abilities, and other factors, many entrepreneurs were constrained by the fear of failure (GEM (Global Entrepreneurship Monitor) (2022)).

## 2.2. Business Sustainable Management

Entrepreneurship and quality management are subjects of a discipline called Business sustainable management, which is concerned about:

- The global state, what needs to change, and how to bridge the sustainability gap through rewiring the economy.
- Why sustainability is good for business, and the importance of good leadership in achieving change.
- Policy instruments, international agreements, and the role of business and civil society in shaping a zero-carbon economy.
- The value chain: Implementing business models and processes for sourcing, producing, and consuming sustainably.
- The role of innovative design,

planning, and technology in facilitating sustainable business.

- How to effectively communicate sustainability strategies and goals to internal and external stakeholders.
- How businesses can work together with corporate, government, and non-profit actors to bring about large-scale change in the sustainability space (Business sustainability management course, 2022).

### 2.3. Entrepreneurship Index

The Entrepreneurship Index, compiled by the CEOWORLD magazine, evaluates a total of 100 economies that collectively account for 95 percent of the global gross domestic product. The overall ranking considers a wide range of factors to create an overall “best countries for entrepreneurship” index, including innovation, competitiveness, infrastructure, labor skills, access to capital, and openness for business.

Starting a business anywhere takes grit, determination, and a marketable idea, but certain economies make it just a little bit easier for entrepreneurs to get off the ground. If you’re looking for the best country to build a business, you may not have to look far.

To determine the rankings, researchers compiled, analyzed, and compared countries across 6 key categories: innovation, competitiveness, labor skills, infrastructure, access to capital, and openness for business.

To evaluate those dimensions, researchers looked at 18 indicators that fell into one of the 6 categories. An index has been created scoring the individual indicators on a scale of 1-100. Each indicator was given equal weighting within each of the 6 categories with some indicators being comprised of 2-3 sub-indicators that were also weighted equally.

The rankings are the result of a rigorous analytical exercise, incorporating multiple data sources, without relying on investment promotion agencies (IPA) and Government Industry trade data submissions.

The margin of sampling error for the full sample of 120,000 respondents is plus or minus 1.2 percentage points. In addition to sampling error, one should bear in mind that as in all survey research, there are possible sources of error, such as coverage, nonresponse, and measurement error, that could affect the results (Business sustainability management course, 2022).

### 2.4. International Standards Organization and Business Sustainability

The International Organization for Standardization (ISO) refers to Sustainability as the ability to maintain or develop performance in the long term. Looking at it through a different lens, sustainability has to do with maintaining businesses financially, socially, and environmentally. Sustainability broadly consists of three components:

- Business Sustainability (economic/financial);
- Environmental Sustainability; and
- Social Responsibility.

Two types of ISO Standards are helpful for the successful implementation of Sustainability practices:

- Certifiable standards
- Guidance standards.

### 2.5. International Standards Organization and Business Sustainability

According to ISO (World Most Entrepreneurial countries 2021 (2022)) governments, industry, consumers, the economy, society, environment, can benefit from using ISO standards as per below.

#### 2.5.1 Government

Regulators can rely on ISO standards as a solid base on which to create public policy that helps further Sustainable Development Goals (SDGs) such as human rights, water, and energy efficiency, public health, and more. Recognized the world over, International Standards also help governments achieve their national and international commitments (<https://www.iso.org/sdgs.html>).

### 2.5.2 Industry

Industry plays a key role in achieving all the SDGs and ISO standards help it do that by providing guidelines and frameworks on everything, from employee health and well-being to energy consumption, to resilient and eco-friendly infrastructures (<https://www.iso.org/sdgs.html>).

### 2.5.3 Consumers

While contributing to the SDGs ranks high on the agenda of business leaders and politicians, many of the benefits are felt at the local community level. Reduced poverty, improved health, cleaner and more abundant water, and safe and secure infrastructures are just some of the benefits to be gained from implementing ISO standards (<https://www.iso.org/sdgs.html>).

### 2.5.4 Economic

ISO International Standards promote economic sustainability by facilitating international trade, improving a country's national quality infrastructure, and supporting sustainable business practices (A quality infrastructure is a system contributing to governmental policy objectives in areas including industrial development, trade competitiveness in global markets, efficient use of natural and human resources, food safety, health, the environment, and climate change). They cover everything from efficient farming

methods to anti-bribery management systems (<https://www.iso.org/sdgs.html>).

### 2.5.5 Social

ISO International Standards promote social sustainability by helping countries and communities improve the health and well-being of their citizens. They cover all aspects of social welfare, from healthcare systems and related products to social inclusion and accessibility (<https://www.iso.org/sdgs.html>).

### 2.5.6 Environmental

ISO International Standards promote environmental sustainability by helping businesses and countries manage their environmental impact. They cover such aspects as implementing an environmental management system, measuring and reducing greenhouse gas emissions and energy consumption, and encouraging responsible consumption (<https://www.iso.org/sdgs.html>).

## 2.6. Quality Management, Doing Business, and Global Trends on ISO Certificates

Quality management is the act of overseeing all activities and tasks needed to maintain a desired level of excellence. This includes creating and implementing quality planning and assurance, as well as quality control and quality improvement. Quality management ensures that an organization, product, or service is consistent. It has four main components: quality planning, quality assurance, quality control, and quality improvement (Rose, 2005). Quality management is focused not only on product and service quality but also on the means to achieve it. Quality management, therefore, uses quality assurance and control of processes as well as products to achieve more consistent quality. Several means to

achieve quality management are between doing business regulations and rules, ISO certificates included, which are focused more on the quality of procedures private and public subjects follow, which at the end of the day brings a higher quality of products and services (Ceko, 2013c).

Because societies need regulation—and businesses, as part of society, are no exception, ISO certificates finally are part of business and trade regulations since they are the minimum requisites for characteristics of processes, products, and services to be used by private and public entities/subjects to be acceptable from their clients and markets. Without this standard,s modern private and public entities cannot exist. And where markets are s left without standards, they would produce poor outcomes and finally low life quality for citizens. When starting a new business, or entering a new phase of enterprise development, entrepreneurs need to establish certain procedures and standards, allowing the business to live beyond minimum frontiers, e, export, and import, participate in public procurement procedures, and finally attract as many as possible clients, for higher profits and

achieving other business objectives. Standards are the heart of all these issues, facilitating business transactions and allowing businesses to operate effectively. With 1 609 294 certificates issued worldwide in 2014, there is a slight up on the previous year, which demonstrates a moderate growth for almost all the ISO management systems standards around the world (<https://www.iso.org/sdgs.html>), confirming trends observed over the last two years. This market stabilization is, however, offset by three good performers exhibiting more sustained growth. Albeit less impressive than in previous years, ISO 50001 for energy management demonstrates a 40 % growth rate, led once again by Germany, responsible for 50 % of the 6 778 certificates reported. Similarly, food management standard ISO 22000 continues to deliver reliable performance with a 14 % growth rate, while ISO 16949 for the automotive sector shows accelerated progression with a commendable 8 %, signaling that economic recovery in the auto industry is holding up (ISO Survey Executive Summary, 2014).

**Table 1.** ISO Survey Executive Summary. 2020 [19]

ISO standards	Total valid certificates	Total number of sites
ISO 9001 – QMS	916,842	1,299,837
ISO 14001 – EP	348,473	568,798
ISO 45001 – HSW	190,481	251,191
ISO/IEC 27001 – ISM	44,499	84,181
ISO 22000 – QSGF	33,741	39,894
ISO 13485 – H	25,656	34,954
ISO 50001 – EE	19,731	45,092
ISO 20000-1 – IT	7,846	9,927
ISO 22301 – BC	2,205	4,662
ISO 37001 – ABMS	2,065	5,946
ISO 39001 – RTS	972	2,341
ISO 28000 - SRMS	520	968

When compared with the 2019 edition, the results are consistent when looking at the overall figures for most of the countries. The overall results show an increase, from 2019,

of 18% in the total number of valid certificates for the 12 management system standards covered in the survey. Part of this significant increase is due to the important

growth in the certification to ISO 45001; this standard was published in 2018 and consequently had a limited number of certifications in the previous edition of the survey. The rate of increase for ISO 9001 and ISO 14001 has been greater compared to previous years with +4% for ISO 9001 and +12% for ISO 14001 mainly due to an important increase in China. Similarly, to the previous editions of the survey, the results show some fluctuations at the country level that are explained by factors related to the participants such as the non-participation of some certification bodies for those specific countries. In the 2020 survey, this is the case particularly for ISO 9001 and ISO 14001 for Belgium, Korea, Mexico, Ireland, and the Philippines and for ISO 28000, China (ISO Survey Executive Summary, 2020).

The most important thing related to this paper is the declaration of the International Standards Organization that the ISO Survey is not a database, but just a list of ISO certificates issued and a list of countries based on alphabetic order, neither based on the number of certificates issued per country ISO (Survey Executive Summary, 2020).

## 2.7. How ISO Standards Help Companies and Bring Benefits to their Clients

As it is stated in the GEM Report Policymakers could allay much of this fear by drawing greater attention to entrepreneurial success stories both large and small and implementing risk-mitigating initiatives that reduce real and perceived impediments for startups (GEM (Global Entrepreneurship Monitor) (2022)), besides other factors, ISO standards help on this issue.

ISO standards have helped various companies and our clients have benefited because of:

Reduced risk: The underlying reason for ISO compliance is that entrepreneurial companies are at a greater risk than established

organizations – and thus have a more compelling case for minimizing risk. If a young company doesn't have policies, processes, and procedures that are standardized, it risks wasting its precious resources. And that doesn't result in just missing the numbers – it can mean going out of business.

**Builds in consistency:** It isn't enough for fledglings to operate with a "general knowledge" of the details involved in turning out first-rate products or services. Typically the founders and a few employees have the needed knowledge but it is not communicated consistently across the organization. ISO standards, by contrast, put policies, processes, and procedures in writing so that everyone is aware and able to work within common directives.

**Measures ROI:** In addition, ISO standards serve as a checklist against which a young company, whose financial talent and systems might not yet be up to par, can measure critical entrepreneurial objectives, namely return on investment or ROI.

**Builds credibility:** Finally, standards function as an imprimatur, convincing partners to engage with, and customers net to buy from, an untested entity (Leo et al., 2003).

## 2.8 Methodology and methods (Research framework, the purpose of the case study)

The framework of the research was the relationship between Entrepreneurship Index (E Index) and the ISO standards Index from a global perspective and global ecosystem. Given the lack of numerical, statistical, and algebraic arguments on relations between the E Index and the ISO Standards Index, this study adopts a building mode theory and aims to investigate the following research questions:

- 1) Ho: There is a strong connection/relation between E Index and the ISO standards Index.

- 2) H1: There is not a strong connection/relation between E Index and the ISO standards Index.

... considering that there is little research on relations between the E Index and ISO standards Index, listed in the literature review of this paper research, and considering that theoretical approaches on relations between entrepreneurship and ISO standards, and specifically between E Index and ISO standards Index, as well as numerical, statistical and algebraic arguments on relations between them, doesn't exist.

Specifically, while acknowledging the importance of connections/reasons between entrepreneurship and ISO standards, prior empirical research impresses with declarations that this connection exists, but does not explain statistically if there is any connection/relation between them, thus, a theory was needed, supported by analysis and evidence. Therefore, with this critical analysis, an exploratory approach was adopted, using a single in-depth case study approach, appropriate for building an in-depth understanding of a phenomenon and allowing closer investigation of theoretical constructs.

### **2.8.1 Case selection**

The case was selected based on three main criteria: a theoretical approach, suitability of relations, and practical positive impacts on relations between the E Index and ISO standards Index.

The case project ran in stages: (1) identifying needs for entrepreneurship, (2) identifying needs for quality management, and ISO standards certification, and (3) identifying the rank of the countries for Entrepreneurship and the Rank of countries for ISO standards Index.

### **2.8.2 Data collection**

Data for E Index has been gathered from Entrepreneurship Report 2021, an annual ranking of countries by their achievement on the subject, compiled by the CEOWORLD magazine (The world's most entrepreneurial countries. 2022).

Data for the number of businesses registered worldwide has been gathered from HitHorizon (<https://www.hithorizons.com/>).

Data for the ISO standards Index has been gathered from the ISO certificates Report 2022 (<https://www.quality.org/article/2020-iso-survey-management-system-standards-reveals-17-increase-certifications>).

To prepare the ISO standards Index I have divided the number of ISO certificates issued per country by the number of businesses registered in the country, resulting in the ISO standards Index per country, preparing the list of countries based on this Index.

### **2.8.3 Data analysis**

A correlation and regressive analysis (inferential statistics) between these Indexes for 91 countries worldwide were performed. In the table below, 91 countries are listed for the E Index, and ISO Standards Index (prepared by the author of this article as per the explanation given in the paragraph above).

Based on these data and information from secondary resources, a regression between E Index and ISO certificates issued per country was built. Data from ISO about ISO standards certificates issued worldwide (taken from ISO report) didn't help directly, because an Index was needed, so the Index divided the number of ISO standards certificates issued per country by the number of business entities in the country, finding the ISO standards Index, as explained above.

### 3. Results

After listing countries per this Index, regression analysis between the E Index and ISO Standards Index was drafted, based on which, it can be stated that the relations between the E Index and ISO Standards Index are not high, verifying the H1 hypothesis which was: “There is no relation between E Index and ISO Standards Index, against Ho that was: “There is a strong relation between E Index and ISO Standards Index”, which is a hypothesis that comes from the highly estimated situation from international organizations and believes of people who work on these subjects, which could never prove this hypothesis statistically.

In table 2, countries are listed as per the E Index, which served as the “Y” at the regression procedures, and ISO standard Index which served as the “X” at regression procedures, handled in an excel program.

**Table 2.** List of countries based on the E Index (CEOWORLD) and the ISO Standards Index (drawn from the author of this paper)

In figure 1 a correlation analysis, in a graphical mode is given, where is shown there is no connection/relation between E Index and the ISO standards Index.

In the three tables below, tables 2, 3, and 4, statistical results about missing connections/relations between E Index and ISO Standards Index are given, where  $R^2 = 0.248363$  shows a weak connection/relation between these two Indexes.

**Figure 1.** Missing relations between E Index and ISO standards Index (graphic is drawn from the author of this paper).

**Table 2.** Summary Output

With these results, it has been verified in practice there is no connection/relation between E Index and ISO Standards Index.

## 4. Discussion

In this study, by making use of a regressive analysis, it was verified statistically that there is no relation between E Index and ISO Standards Index, but this doesn't mean the relations are not needed, or they can't be achieved in the future. The question is when these relations will be achieved and verified, and what is needed next.

It is true and we all, World Bank, United Nations, and ISO including, do believe that entrepreneurship is important for economic growth and there is an improving ISO standard certification process all around the globe, but the question is how we can better match and adopt the entrepreneurship activity with ISO standards.

Scientific management of factors of production creates opportunities for improving entrepreneurship climate and business activity, applying quality management principles and ISO standards, as efficient and effective tools, and this is needed, immediately, but scientific management of factors of production requires ISO standards application in a wider approach and not only for private subjects which are looking to participate in public

procurements as well as for exporting goods accompanied with ISO certificates, so, a real connection and relations between the E Index and ISO standards should exist.

### 4.1 Implications for Theory and Practice

About the theory, based on the final results of this research, a new window has been opened for further research in the field of relations between entrepreneurship and quality management, and especially between E Index and ISO Standards Index, considering them as a tool for a life quality improvement all around the world.

#### *Contribution*

The contribution of this paper, mostly on the field of relations between entrepreneurship and ISO standards, shows that international organizations, those mentioned in this paper, should carefully investigate the issue of building research relations between concepts, especially between important concepts and principles like those of Entrepreneurship and Quality management principles too.

This critical analysis article emphasizes the economic and social importance of Entrepreneurship and ISO standards, for current and future generations.

**Limitations and Further Research**

This research has been undertaken using plenty of data about the E Index and offering for the first time information about the ISO Standards Index for the period of 2020.

Further research is needed to verify these relations, which must be stronger in the future, to make Entrepreneurship Index and ISO Standards Index real tools for life quality improvement all around the world.

**5. Conclusion and Recommendations**

Scientific management of factors of production creates opportunities for entrepreneurship activities, applying quality management principles and ISO standards, as efficient and effective tools, and this is needed, immediately.

Scientific management of factors of production requires ISO standards application; so, a connection and relations between the Entrepreneurship Index (E Index) and ISO standards should exist, for healthier business ecosystems.

The general outcome of the research is looking forward to achieving and maintaining entrepreneurship activities, applying quality management principles and ISO standards, as efficient and effective tools, as an immediate need, all parties should look forward to making sure building relations and connections between Entrepreneurship Index and ISO Standards Index, which currently doesn't exist.

There are no strong and sustained relations between sustainable development and quality management/ISO standards.

Improving quality management system / respecting ISO standards parallel with working on improving the business climate and strengthening entrepreneurship activities, shall have a real indication of life quality improvement all around the globe.

There is no relation between entrepreneurship and ISO standards, even though it is assumed that it should exist to promote sustainable entrepreneurship with no support at all.

## AN INVESTIGATION INTO TQM IN A RETAIL BANK IN THE KINGDOM OF BAHRAIN

**Abstract:** *TQM is a must if you want to improve policies and procedures and make customers happier. The paper investigates total quality management (TQM) implementation in a retail bank in Bahrain. The study distributed 131 questionnaires, of which 120 have been returned. The results showed that TQM improves operations and functions by involving and training employees. TQM was perceived as a strategic technique to enhance the bank's profitability. Employee involvement, training, strategic planning, and top management commitment correlated positively with TQM. The study suggests that retail bank employees keep quality standards and get regular training and education to help provide good care.*

**Keywords:** *Total quality management, retail bank, management development, banking sector, and Bahrain*

### 1. Introduction

Quality has become one of the best ways for all organizations to stay in business and do well [1]. To excel in quality, firms must add value to their customer service. TQM is a strategic system for customer satisfaction in today's dynamic and competitive environment that assists managers in evaluating external environments. The concept of total quality management (TQM) meets the organization's goals by facilitating customer satisfaction at the most economical level. The former name of TQM was quality control. TQM refers to the philosophy of business management that helps recognize the customers' needs and the organization's inseparable goals [2]. In today's dynamic and competitive environment, strategic management is critical to assisting managers in evaluating external environments. An effective TQM strategy allows organizations to optimize resources to extract opportunities

and limit threats to achieve competitive advantage [3].

TQM is the way of thinking and acting needed to give customers a good product and meet their needs. TQM described quality as the giving force behind guidance, preparation, and enhancement. Communication among all employees is necessary to ensure proper and efficient management of quality issues and measures, whether at a lower, middle, or higher management level. Padhi [4] categorized TQM into eight elements: the binding mortar, building bricks, foundation, and roof. Critical, or communication, refers to understanding the sender and receiver. A successful TQM requires active communication between employees, customers, and suppliers.

The building blocks category includes teamwork, training, and leadership. Collaboration ensures the smooth running of the organization. People feel free to bring

Email: [malshammari@uob.edu.bh](mailto:malshammari@uob.edu.bh)

challenges, and the management gets the operators' help finding the solution. Successful companies in the future will encourage teamwork, cooperation, and employee connections to their business partners and clients, as well as greater employee inclusion in the company's development activities. Similarly, training is essential to increase the productivity of the employees. It helps employees improve their skills, such as problem-solving, decision-making, etc. The learning or training curve can be improved using a short creation period, seminars and courses, co-working space, divided teams, cohort peers, and mentorship. Leadership is one of the essential elements in TQM. The supervisor led the employee to understand the strategic direction of the company. The leader understands the concept of TQM and teaches the employees through their daily practices.

Under the foundation come integrity, ethics, and trust. Integrity specifically discusses or includes factors such as morale, value, and honesty. On the other hand, ethics are related to the discipline maintained in excellent or harmful situations. Personnel decisions are related to standards. Trust is the output of integrity and trust. The framework of the TQM is built on faith. It encourages ownership and commitment. Trust ensures customer participation and makes the company environment suitable for work. Acceptance or recognition is the final step in the complete system. It provides individual and group recommendations, recognition, and acceptance to the employees trying to receive credit for their group and themselves. Recognizing individual contributors is the supervisor's responsibility.

Putting a QM theory that has already been tested in a new situation adds to its theoretical value [5], especially in developing economies. This research aims to bridge this literature gap on the role of TQM in a developing country's setting. The main goal was to examine the relationship

between employee involvement, employee training, strategic planning, top management commitment, and TQM in a local retail bank in Bahrain. The study investigated many issues concerning the valuation of quality. The study has been extended to include collecting primary data and statistical analysis so that practitioners can use actual and accurate materials.

## **2. Methodology**

### **A. Instrument**

The five-point Likert scale questionnaires were electronically distributed to the respondents through Google Forms. The web link was distributed to the randomly selected employees by email.

### **B. Sampling Method**

The study used a simple random sampling technique to collect data, where every subject had the same chance of being selected [6]. Simple random sampling necessitates little prior knowledge of the population [6], and telephone interviews have been used to follow up with respondents.

### **C. Sample Size**

The respondents were managers, executives, and middle-level employees. Out of these 131 distributed questionnaires, 120 were returned. Thus, the response rate for this study was 91.60 percent.

### **D. Research Variables**

**Employee involvement:** All employees must participate for organization members to participate in the quality control process. It will result in the assurance of a proper TQM process.

**Strategic planning-** Adequate physical resources are also essential for reasonable quality control assurance. To correctly manage the quality within organizations, there must be sufficient material resources to ensure quality control and management

strategies.

Employee training helps employees understand the need to maintain the organization's quality issues. Training has always been an important tool to motivate employees to control and manage quality problems and factors. It makes the employees responsible enough to accomplish their duties to assure quality control and leadership within the organizational aspects.

The commitment of top management- Top management is primarily responsible for maintaining and overseeing all quality management issues. They must govern all other members to ensure proper administration of the organization's TQM. The organization's top administration can make the other employees indulge and be motivated towards the appropriate management and control of all the quality issues.

### 3. Results

Most respondents were employees for more than seven years, 43.33%. Most employees had 5-7 years of experience (24.17%), followed by employees with 3-5 years (20%). The minority employees had less working experience (less than three years, 12.50%). The most significant demographic feature was that most of the respondents had a total work experience of more than seven years.

#### A. Reliability and Internal Consistency

Table 1 provides Cronbach's alpha test results for 120 participants using SPSS version 20. According to Tavakol and Dennick [7], as Cronbach's alpha is more significant than 0.7, it is considered acceptable. Table I demonstrates that Cronbach's alpha minimum value was 0.733 and the maximum was 0.953, along with Cronbach's alpha value for the whole questionnaire being 0.975.

**Table 1.** Reliability and internal consistency

Construct	No. of Questions	Items	Cronbach's Alpha (Reliability)
TQM	4	Q1-Q4	0.808
Employee Involvement	4	Q5-Q8	0.733
Employee Training	4	Q9-Q12	0.953
Strategic Planning	4	Q13-Q16	0.952
The Commitment of Top Management	4	Q17-Q20	0.951

#### B. Perceptions of TQM

The general perception of TQM had a mean of 3.08. The statement "All the bank employees strive to meet their needs and expectations" had a mean score of 3.55. The statement "Quality is the key strategic factor in achieving business success" had an arithmetic mean of 3.30. The statement "TQM is the procedure or technique for improving the bank's reliability, efficiency, and quality," with an arithmetic average equal to 2.99. Finally, "TQM is the management approach the entire bank follows" equals 2.48.

As for the perceptions of employee involvement, the mean score of the statement "Employees of the bank are always involved in offering a high quality of work" was 4.53, followed by "Participation of all the organization members determines high quality in the group," with a mean of 4.50. Then "the involvement of employees is also the primary element of TQM" had a mean of 3.27. Lastly, "employees are the main way to keep and ensure quality in the organization," which got a mean score of 2.96, got the lowest score.

The general mean score of the perception of employee training was 3.82. The mean average of the statement "Training will also make them aware of the need for quality control for ensuring proper organizational proceedings" was 4.25. Then "Training and development programs help the employees to know about their goals and objectives in the organization," with a mean of 4.18. Then, "Training that can make employees understand the need to manage quality within the organization" with a mean score of 3.94. Finally, "All the bank employees are provided with training for showing high-quality performance," with a mean of 2.91. The section was rated 4.09 by the general mean of strategic planning perception. The mean average was 4.58 for the statement "TQM is the strategic planning that involves continuous improvement of product quality to achieve customer satisfaction," followed by a mean of 4.53 for the sentence "TQM is the strategic planning of the organization." Then, "Strategic planning accomplishes the primary task or duty of maintaining quality issues within the organization," with a mean of 3.69. Finally, "To ensure the proper TQM process in the organization, it is vital to synchronize TQM and strategic planning,"

with a mean of 3.55. Table 5 shows that the arithmetic mean of the section was 3.32.

The general mean of the perception of top management commitment was 3.32. The mean score for "Top-level management of the organization arranges for organizational innovation to ensure high-quality work" was 3.69, followed by a mean score of 3.46 for "Top-level management of the organization arranges for organizational innovation to ensure high-quality work." The statement "A bank follows TQM programs with the help of top management support" had a mean score of 3.18. Finally, "All the organization members are responsible for maintaining high-quality products and services to gain customer satisfaction" had a mean score of 2.96.

**C. Correlation Coefficient Results**

Table II documents the Spearman correlation coefficient results. The correlation coefficients exceeded 0.7, referring to high relationships between the study variables and the p-values, which were less than 0.05. The results showed significant associations between employee involvement and training, strategic planning, and top management commitment to TQM.

**Table 2.** Spearman's correlation coefficient results

		Correlations				
		TQM	Employee Involvement	Employee Training	Strategic Planning	Top Management Commitment
TQM	Spearman's $\rho$	1.000				
Employee Involvement	Spearman's $\rho$	.894**	1.000			
Employee Training	Spearman's $\rho$	.916**	.871**	1.000		
Strategic Planning	Spearman's $\rho$	.917**	.858**	.921**	1.000	
Top Management Commitment	Spearman's $\rho$	.935**	.902**	.968**	.934**	1.000

**4. DISCUSSIONS**

TQM became a critical way to improve and enforce policies and procedures so that customers could get value-added benefits. Employees' satisfaction with TQM as a

strategic management technique was consistent with the findings of Hosseini et al. [8] regarding achieving long-term competitiveness.

The results indicated a positive and significant correlation between employee involvement and TQM. This result is similar to that of Fotopoulos and Psomas [9], who explained that employees are the primary determinant that helps maintain quality issues and control the maintenance of products or services.

The relationship between employee training and TQM provided a positive result. Providing proper employee training and development programs is a significant responsibility for the bank and higher-level managers. This result was consistent with Padhi [4], Salamzadeh et al. [3], and Salamzadehand Radovic-Markovic [11], who explained that training is crucial to increasing employees' productivity. Training helps employees improve their skills, such as problem-solving, decision-making, etc. Management competencies and skills help to oversee TQM issues with the proper skills and knowledge. Knowledge development and human resource capabilities are essential because increasing human resource capabilities play a significant role in achieving strategic objectives and public satisfaction.

The correlation between strategic planning and TQM provided a positive relationship between these two variables: strategic planning and TQM. Strategic planning is essential to ensuring and handling all the quality problems in the bank. According to Sallis [12], TQM is a management strategy incorporating quality elements into the organization's management process. The concept of TQM needs to be nurtured within the culture of organizations. The organization needs specific plans to raise its standards in the policies and procedures related to its quality issues.

The correlation between top management and TQM commitment again provided a positive result, indicating that top management and TQM commitment variables had a positive and significant

relationship. The top management's commitment to quality management cases is as fundamental as their participation in quality control issues. It is the highest required duty that needs to be accomplished by the top managers in the maintenance of quality control, which will again motivate the other employees of similar banks to take the initiative in maintaining quality issues. Furash [13] also found that top management had a unique role in maintaining and managing the TQM programs.

## 5. Conclusion

In the banking sector, service quality is an important aspect. The business's success depends on effective ways to improve the organization's performance. When the TQM is defined and implemented, it provides the marketer with an unobstructed view of the bank's elements as the first choice for new and existing customers.

Quality needs to be the top priority of the administration. To build a service-quality culture in any organization, the leadership and participation of the management play a crucial role. Thus, this study produced the combined result that TQM issues need to take particular concern over factors such as employee involvement, training of the employees, strategic planning, and the commitment level of the bank's top management. Considering the competitive environment in the banking sector, there is a great need to develop TQM programs in operations and functions.

The retail bank's management needs to ensure that the staff learns more about TQM's importance to the bank's long-term competitive advantage. Employees need regular training and education on TQM practices that can change their beliefs, attitudes, and actions. Employees must know about human resource development projects and be encouraged to participate. There also needs to be a system of rewards and praise

for employees who work to improve quality. regularly evaluated and constantly improved.  
The TQM practices of the bank need to be

## INTEGRATING CONSTRUCTS OF THE TECHNOLOGY ACCEPTANCE MODEL AND TOTAL QUALITY MANAGEMENT TO IMPROVE DOCUMENT MANAGEMENT PERFORMANCE

**Abstract:** Document management processes represent a key consideration in business success and quality management. There is ongoing pressure for the public sector to embrace these tools to increase efficiencies, reduce cost, waste and more significantly upholding their mandate of improved services to its citizenry. An exploratory sequential mixed method comparative case study design described the study's methodology. The study relied on the combination of a desktop review; semi-structured exploratory individual interviews (n=45) with municipality executive and strategic managers; focus group discussions (n=2) comprising 5 and 7 participants each and a quantitative online survey (n=186), in which executive/strategic municipal employee participants provided experiential insights into the range of factors that influenced technology acceptance of differing document management systems, whilst simultaneously offering their insights on the range of impacts on "total quality" that they experienced and observed. This study reports on the quantitative part of the study. The South African context creates a unique dynamic and, for that reason, traditional models related to technology acceptance were found inadequate. The recommendations borne out of the findings can contribute substantially towards a more in depth and incremental understanding towards the successful, implementation and adoption of a customised, purpose-built document management system for the public sectors.

**Keywords:** Document management processes, increase efficiencies, reduce cost, waste, exploratory sequential mixed method, TQM and TAM, South Africa

### 1. Introduction

A range of document management system alternatives have been widely introduced globally (ranging from print-based, hybrid and paperless) but their success and usage patterns is varied because of the differing

conditions under which each has been implemented. Global reports of business running costs suggest that poorly evidenced document management systems can increase running cost wastage for companies by anything from 15 percent to 65 percent of the total business running cost when compared to evidenced options and in the

main, these cost differences can be the fine-line between the survival or demise of a business entity (Helmer 2012). By the same token, environmental sustainability of different document management processes represents an important consideration in business success and quality management. Some, including Jones (2012) and Marton & Choo (2012) suggest that strategic decisions related to, choice, usage and overall quality contribution of document management systems within business have its historical roots, in the total quality management discourse and constructs related to technology acceptance. Coined in 1985 by the USA navy, the theory of Total Quality management (TQM) is conceptualised.

## **2. Research problem**

Documents represent the single most universally utilised form of communication within businesses and their management is identified by some, as one of the top sources of financial wastage (Welsh, 2007) and (Department of Health and Hunt, 2013). Some, including Ugale, Patil and Musande, (2017) and David, Ngulube and Dube, (2013) have presented studies that show that up to 15% of fruitless expenditure within business is attributable to the mismanagement of document management systems especially within publicly run enterprises. Evidence has been consistent in illustrating a need for more evidence-based understanding of the problems associated with paper/document management systems as part of the wider agenda of increasing efficiencies and driving down operational costs. This is especially important within public entities because government reports from various contexts globally, show a growing lack of funds for the necessary operations and service provision that have direct impact on the wellbeing and the health of populations (McGrath, Griffin & Mundy 2016) and (McMullen 2011). The use of

paper within industry has been equated to millions of tons of deforestation and beyond the search for efficient document management options., there is a need for seeking out options that are not harmful to the environment. This unresolved challenge represents a significant problem for the public service, one that is deserving of empirical study.

## **3. Literature review**

Documents represent the single most universally utilised form of communication within businesses and their management is identified by some, as one of the top sources of financial wastage (Welsh, 2007) and (Hunt, 2013). Some, including Ugale, Patil and Musande, (2017) and David, Ngulube and Dube, (2013) have presented studies that show that up to 15% of fruitless expenditure within business is attributable to the mismanagement of document management systems especially within publicly run enterprises. a growing lack of funds for the necessary operations and service provision that have direct impact on the wellbeing and the health of populations (McGrath, Griffin & Mundy 2016) and (McMullen 2011). Beyond the wasteful expenditure and efficiency imperatives, the attention given to more effective management of documents has been equalled by growing concerns related to the environmental sustainability of paper-based document management systems. The use of paper within industry has been equated to millions of tons of deforestation and beyond the search for efficient document management options., there is a need for seeking out options that are not harmful to the environment. With this imperative clearly accepted by many including Al-Yahya and Panuwatwanich (2018), there have been significant efforts and debates across industry to determine how businesses can bring about greater efficiencies in the workplace, particularly with respect to the

management of documents.

### **3.1. An overview of the value of electronic document management systems – debates about paper-based and electronic options**

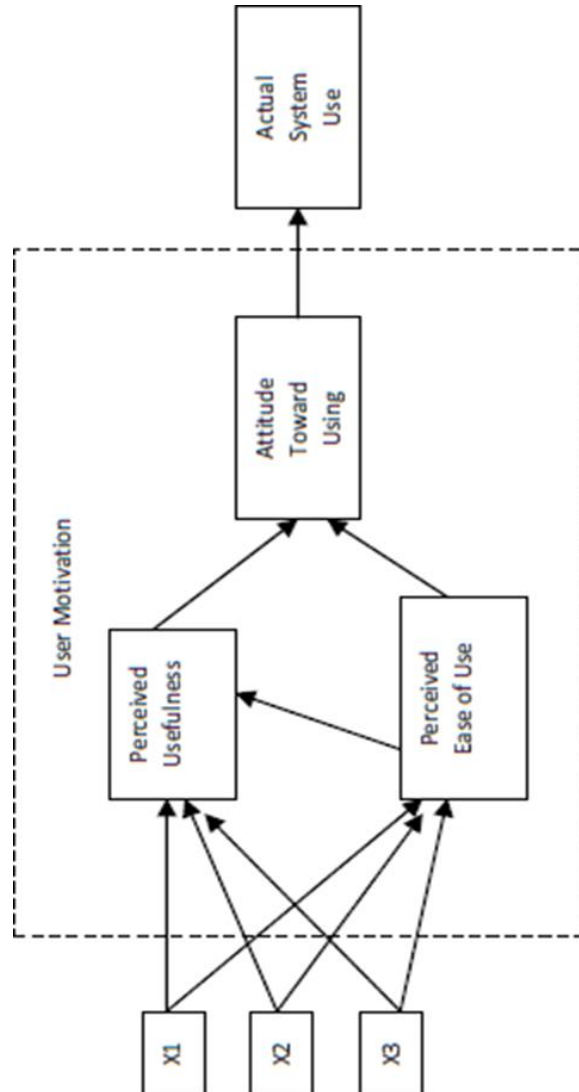

Firstly, there appears to be some contradictory evidence about the benefits and limits of electronic systems, for example, Igbaria et al., (1997) show EDMS to be disproportionately expensive at the point of initiation, that many services and organisations often do not possess the material resources to effectively oversee their introduction. As much as this is not a distinct disadvantage, it represents a critical acceptance factor that can dissuade use of newly introduced innovations. Furthermore, others including Hsu & Chiu (2006) show that the introduction of new technologies is usually problematic because potential users are inadequately trained and as such, the full potential of the new technology is never realised. As noteworthy as these summations are, Horst et al. (2007) put forward the view that these shortcomings are not specifically about EDMS but rather speak to poor implementation readiness issues. Others including Featherman and Pavlou (2003); Grandon and Pearson (2003) and Heinze and Hu (2007) identify the benefits of EDMS over traditional manual methods of paper management. Notably, Gilani (2009:16) and Kunis (2007:31) argue that, within public services, the debates about the acceptance of different document management systems have noted the specific benefits of EDMS as ranging across several issues including – cost efficiency, environmental sustainability, quality management and efficient business function. With respect to cost efficiency, Liu and Stork (2000:24) and Vallis (2009:71) argue that, the adoption of electronic document management options can result in anything from 10 percent to 50 percent of total cost reductions.

### **3.2. Theoretical contribution to understanding technology acceptance model – A brief overview of seminal contributions**

The Technology acceptance model (TAM) specifically and critically explores the role that identified factors such as the perceived ease of use, the perceived usefulness ended the probability of system use, all play in determining the likelihood of full implementation of the newly introduced Information Systems. Critically, the TAM prioritises the tracing of the impact of external factors on internal cognitions, beliefs, attitudes and intentions. As a basis of its application, the TAM was derived from earlier work by Azjen& Fishbein (1969) in which they proposed the theory of reasoned action (TRA) (Azjen& Fishbein 1980). The theory of reasoned action offers insights to understanding the voluntary behaviour of individuals. It argues that intention to perform a certain behaviour precedes the actual behaviour and results from a belief that performing the behaviour may lead to particular (often beneficial) outcome. Therefore, stronger intentions lead to an increased likelihood that the behaviour of interest will be performed.

Together, the TRA and the TAM offer a widely accepted viewpoint, which centres on stating that external factors play an indirect role in influencing attitudes, perceived boundaries of normality and how these psychological factors have a significant impact on individual decisions to take up new technologies. Legris et al. (2003) specifically test the application value of these two theories combined together. In their review of literature, Legris et al. (2003), consult over 80 Scientific publications (published between 1980 and 2001) as the basis for identifying the empirical value of the TAM and the TRA. For example, the TAM has been integrated with the Theory of Reasoned Action (TRA))

successfully as a basis for expanding current theories about the factors that impact technology usage.

**Figure 1.** Davis' Original Theory of Technology Acceptance Source: Davis, 1986

Davis' original conception of the TAM has been revised by himself and others over the course of time with the most current version

showing inclusion of wider determining variables as indicated below in Figure 2.

**Figure 2.** Davis' revised Theory of Technology Acceptance Source: Davis, 1986

It should be noted that Davis (1985) attributes the genesis of his TAM to the Theory of Reasoned Action by Fishbein and Ajzen (1975) which identifies that primarily,

an individual's intention to adopt a behaviour is the single most important predicting factor in their decision to act. Fishbein and Ajzen (1975, 1991) importantly

highlighted that the determination of behavioural intention is a result of the combined interplay between a person's attitudes toward that behaviour; their perceived control of the behaviour and any

subjective norms that they would have assumed with respect to the behaviour or in this case, the adoption of a new technology. The TRA is depicted below in Figure 3.

**Figure 3.** Theory of Reasoned Action (TRA) (Source: Fishbein & Ajzen, 1975)

Some researchers, including Silva et al. (2014) suggest that strategic decisions related to choice, usage and overall quality contribution of document management systems within business have their historical roots, in the total quality management discourse and constructs related to

technology acceptance. As such, the theoretical grounding of the study refers both to theory related to total quality management and technology acceptance theoretical areas. The former i.e. total quality management theory is particularly important because it confirms the widely held view that much of

the changes that are introduced in industry are a result of the competitive pressures and the need to satisfy the range of customers that any service has to satisfy. In this regard, Total Quality management represents an important strategy for ensuring stakeholder satisfaction. For the purposes of the current study, it is important that a sound understanding of founding philosophies, concepts and primary principles is elicited.

### **3.3. Total quality management theory: A conceptual overview**

Some researchers, including Silva et al., (2014) suggest that strategic decisions related to choose, usage and overall quality contribution of document management systems within business have their historical roots, in the total quality management discourse and constructs related to technology acceptance. As such, the theoretical grounding of the study refers both to theory related to total quality management and technology acceptance theoretical areas. The former i.e. total quality management theory is particularly important because it confirms the widely held view that much of the changes that are introduced in industry are a result of the competitive pressures and the need to satisfy the range of customers that any service has to satisfy. In this regard, Total Quality management represents an important strategy for ensuring stakeholder satisfaction. For the purposes of the current study, it is important that a sound understanding of founding philosophies, concepts and primary principles is elicited. Although a long-standing issue, the importance of TQM as a strategic focal point is a recent emergence and some, including Jung and Wang (2006) see it as a reaction to the growing customer demands for quality

‘fit-for-purpose’ products. With regard to the development of document management systems, total quality management is the primary motivation for effecting any change in the choice of system that an organisation that uses.

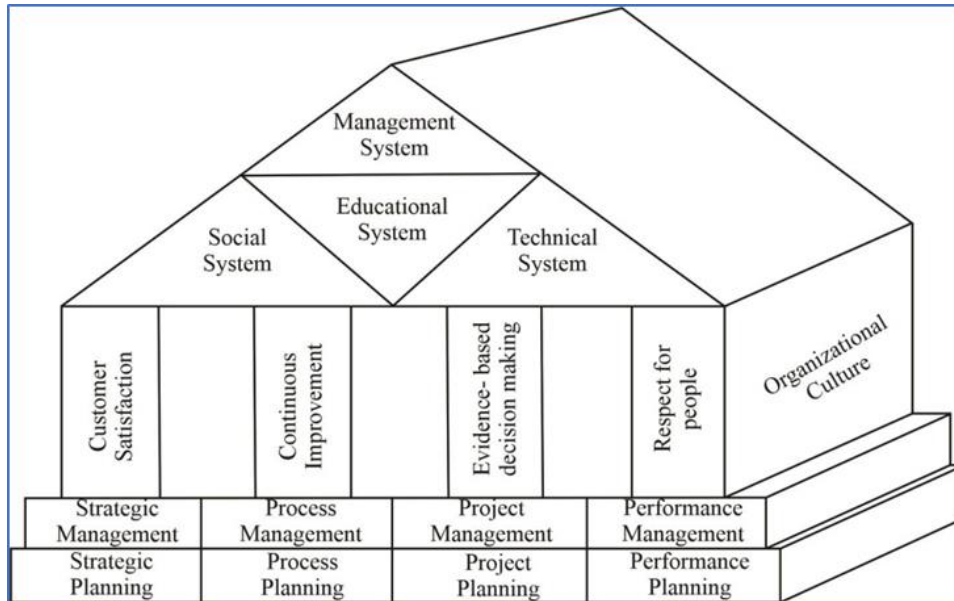

### **3.4. A summative overview of key elements of TQM**

Literature on Total Quality management has been collated and reviewed by a number of theorists including (Excellence 2001) and Holmes and McElwee, (1995) with the primary aim of providing a conceptual overview of what its key elements are. Some including Zbaracki (1998) suggests that there are six major components to TQM;

- Management commitment and leadership
- Employee involvement
- Continuous improvement
- Supplier Quality assurance and management.
- Customer focus
- Education and training

### **3.5. An integrated model for TQM**

The above discussions provide an overview of the different concepts and/or elements of TQM. Geraedts, Montenarie and Van Rijk (2001) and Tapiero (1990) acknowledge that TQM is, by its very nature, a complex phenomenon because of the many considerations that should be made in understanding what quality is and who it is who is defining it. Deming (2001) cited in Swinton, (2004) proposes a building-block theory of TQM which attempts to collate the differing aspects of TQM into a diagrammatic representation below.

**Figure 4.** The House of Total Quality Model (Source: Voehl, 1992)

The above “House of Total Quality Model was initially posited by F. Voehl in 1992 and is made up of six elements that combine house and architectural metaphors with important quality concepts to describe the different aspects that should be considered within any quality discussions. Voehl’s six elements include:

1. Subsystems of the organisation, such as management system, education, social and technical subsystems (roof).
2. Continuous improvement of customer satisfaction, basing decisions on facts and respect for people (pillars of quality).
3. Strategic management, processes, projects and tasks (base).
4. Strategic planning of processes, projects and tasks (benches).
5. Development of organization (mortar).
6. Corporate culture (the wall).

The above-identified House of Total Quality model shows the wholly inclusive approach to quality management and any

implementation of any quality management process should be centred on the operationalisation of key organisational processes, methods and techniques. This wide-encompassing view has been used within the current study to inform that way in which quality issues have been explored.

### **3.6. Application of the theoretical framework in this study**

As indicated earlier, the combined exploration of concepts related to technology acceptance and total quality management is used as a basis to guide both the data collection and analysis processes. To that end, the resulting data collection procedures are designed to ensure inclusion of each of the factors/influences and variables that the theories highlighted. Furthermore, the decision to collect data from the varied perspectives of different stakeholders within the document management sphere was largely informed by explorations of relevant theoretical framings of the subject under study.

## 4. Methodology

### 4.1. Research paradigm

Polit & Becker (2014) define epistemology as the philosophical study of the nature, origin, and limits of human knowledge. Within the current study, a number of research paradigms were deemed relevant and as such, each is discussed;

Interpretivism is a paradigm that maintains that all human beings are engaged in the process of making sense of their worlds and continuously interpret, create, give meaning, define, justify and rationalise daily actions (Babbie & Mouton 2001:28). Hermeneutics has a partial resonance with the current study because some of the focus is on how individuals' experience changes upon the introduction of a new technology and that understanding of the phenomena should be based on the lived experience.

### 4.2. Population and sampling

The total target population for the current study was 364 potential participants ("Integrated Development Plan Annual Review", 2016/2017). Parent /source population = 23,000 employees employed by the municipality and who utilize the services of the administration unit. The epi-info sampling calculator ([www.epi-info.com](http://www.epi-info.com)) was used to calculate the sample size and calculations were carried out using the following population parameters:- Target Population = 364 respondents comprised of Mayor (n=1); Executive Committee (EXCO) (n=10); Councillors (n=206); City Manager (n=1); Deputy City Managers (n=6); Heads Of Departments (n=80) and operational staff (n=20). This is a total of 364 respondents within the target population.

A confidence level of 95% and a confidence interval of 5%, were used and based on these, the predicted sample size was 168 respondents. To allow for attrition, a further

10% was added to the sample size i.e. 17 respondents, culminating in a total of 186 respondents being recruited to take part in the survey.

The research study was carried out over four phases, which included focus groups, semi structured interviews and a survey questionnaire. This study will focus on the quantitative analysis only.

## 5. Data Presentation:

The final data collection phase of the study was a questionnaire-based survey in which identified respondent groups were represented.

As per sampling plan, a total of 186 respondents took part in the survey aspect of the study.

The sampling plan for the survey (Phase 3) was based on a Parent/Source Population = 23,000 employees employed by eThekweni and who utilize the services of the administration unit.

The target population was made up of 344 respondents comprised of Mayor (n=1); Executive Committee (Exco) (n=10); Councillors (n=206); City Manager (n=1); deputy city managers (n=6); Heads of departments (n=40) and Deputy Heads of Departments (n=80).

Through simple randomized sampling, a total of 186 survey respondents from the parent or source population took part in the survey.

The survey focused on eliciting feedback from respondents about the factors that respondents believed to be influential in determining their selection, uptake, and consequential utilization of an electronic DMS.

The replication of this inquiry within a quantitative survey was intended to assess the extent to which findings from previous phases of the study could be generalizable to

wider population groups.

### 5.1. Data Analysis and Interpretation:

The sample of management respondents who took part in the online survey had the highest representation of 30-39-year-old (n=43; 23.19%) followed by those aged between 50-59 years old (n=36; 19.35%).

Notably, the cohort included three respondents who are under the age of 19 years old, and a significant proportion were aged between 59 and 65 years old (n=31, 16.67%).

Respondents were asked to provide information about their highest educational level attained, and from this process, more than half of the respondents (n=96; 52%) indicated that they had reached or attained at least a secondary school level of education.

Those with at least a tertiary education qualification represented 32% (n=59) of the respondent.

Most of the respondents had been employed within their current positions for at least three years and, as such, were expected to have sound awareness of their role expectations and most importantly what the key document management system requirements were.

The findings from the current study suggest that respondents were adequately experienced in their respective positions and therefore could offer meaningful insight into the barriers and motivating factors for their decisions to use (or not use) electronic document management systems.

Data was collected from respondents about their self-assessed competence in information technology (IT). This variable was identified as a factor of interest as predecessor research (Ammar and Ahmed,

2016) has shown that perceived competence in IT can have an influence on motivation to uptake a new technology.

Over half (n=94; 51%) of the respondents identified themselves as having "basic-user" competencies in IT. 34% (n=64) and 15% (n=28) of the respondents indicated intermediate and advanced user status, respectively.

The current study's developed conceptual framework is a combination of the modified Technology Acceptance Model (TAM), the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh, Morris & Davis, 2003), and the Total Quality Management Theory (TQM) (Silva et al., 2014). These frameworks directed the researcher to a number of variables of interest, including attitude towards use, perceived cost, perceived ease of use, perceived usefulness, satisfaction and enjoyment, subjective norms, behavioral control, perceived security, perceived risk, perceived compatibilities, individual mobility, and personal innovativeness.

To collect feedback on these variables, respondents were asked to provide their opinions, ranging from strongly disagree to strongly agree, on a number of statements related to the above-specified themes. The responses offered by the survey participants for each investigated theme are presented below.

For the theme of "attitude towards use," 147 (79%) of the respondents either strongly disagreed, disagreed, or had neutral opinions regarding the influence of attitude towards use and its impact on whether it influenced their choice to use a specific Document Management System (DMS). The complete overview of the respondent responses for this theme is presented in the table below.

**Table 1.** Attitude towards use

Question (Theme: Attitude Towards Use)	Strongly disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly agree (5)
My pre-existing attitudes towards any document management system plays an important role in deciding whether I use it.	20	102	25	24	15
The attitudes of colleagues towards any document management system are likely to influence me in similar ways and will drive my decision to accept this technology	33	73	40	29	11
I accept that my attitude towards any document management system does not have any bearing on whether or not I decide to use it.	10	8	47	86	35
Using the latest document management system will earn me support and favour from my peers and my management.	29	59	55	23	20
My attitude toward accepting a new document management system may affect my performance and that of the rest of the department in which I work.	10	30	40	60	46

One close assessment, respondents feedback on the five domains that are related to attitudes towards use, broadly indicated that individuals felt that their attitude had limited influence on the decision about whether to use the newly introduced document management system. In summation, individual attitude towards a specified document management system was seen as having minimal influence on the ultimate decision on whether or not to use that specific alternative. Perceived costs will feature next.

## 5.2. Perceived cost

The rationale here was to attempt to measure the impact of the perceived cost on participants' behaviors with regard to using and adopting new innovation and technology. TAM is extensively accepted as a guide to understanding user's acceptance behavior. Perceived usefulness and Perceived ease of use are the core determinants of individuals' intention to accept or reject new technology. While TAM is used as the baseline model, perceived cost is viewed as an additional independent variable (Rind, Hyder, Saand, Alzabi, Nawazi & Ujan, 2017).

The table that follows is indicative of the respondent's behaviors with regards to acceptance or rejection of new innovation or technology.

**Table 2.** Perceived Cost

Question (Theme: Perceived Cost)	Strongly disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly agree (5)
My perception about the fairness of the cost of the proposed document management system is an important consideration in whether or not I decide to accept and adopt that system.	48	75	48	10	5
The perceived cost of any document management system has no influence on my decision to accept and/or adopt this system.	7	4	12	98	65
Cost of a newly introduced document management system represents one of the most important determining factors that influences acceptance of that system.	59	65	40	15	7
The cost of any new system determines its quality.	24	66	53	10	33

With regard to the fairness of the cost impacting their decision to accept or adopt the innovation, participants 75 (n=40%) disagreed, with a further 48 (n=26%) strongly disagreeing with the statement with regard to their acceptance or rejection of the innovation. Participants 48 (n=26%) remained non-committal. In summation, the

majority of respondents 123 (n=66%) held the view that the fairness of the cost is not a consideration when adopting new innovation. The next determinant to be discussed will be Perceived Ease of Use.

### 5.3. Perceived ease of use

The Technology Acceptance Model (Davis et al. 1989) is a measure of the relationships of Perceived Ease of Use (PEOU), Perceived Usefulness (PU) and Attitudes aligned to Behavioural Intention (BI).

PEOU is one of the determinants that participants must embrace for the adoption and acceptance of new technology. Understanding the participants' perceptions may help to increase the sustained use and adoption of new innovation. The following table is a numerical summary of their Perceptions regarding Perceived Ease of Use.

**Table 3.** Perceived ease of use

Question (Perceived Ease of Use)	Strongly disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly agree (5)
I will not use a system that I view as difficult to use regardless of how much it is likely to improve job performance.	37	80	32	23	14
I am not deterred from using a DMS by its apparent difficulty in use.	16	23	40	72	35
I accept that all new systems will be difficult to use.	17	30	38	65	36
I believe that perceived-ease-of-use is one of the key most important determining factors which influence my decision to use any DMS.	14	13	28	82	49
Difficulty in using a DMS is often a result of computer literacy more than anything.	29	43	71	33	10

Five position statements were included to test the Participants perceptions with regard to Perceived Ease of Use. With regard to the first position statement about not using a difficult system irrespective of job performance improvement, 80 (n=43%) disagreed with the statement. Simply put,

these participants were of the opinion that the improvement in job performance or ease of use far outweighs that of a difficult system or invention. A further 37 (n=20%) held the view that they too will also accept the system irrespective of the difficulty factor by strongly disagreeing with the

position statement. The next determinant to be discussed is Perceived Usefulness.

**5.4. Perceived usefulness**

Initially informed by the technology acceptance model (TAM), perceptions

related to the usefulness of any new innovation were seen as having some relevance on whether or not individuals take up the innovation. The table below offers a numeric summation of the responses in relation to the theme of perceived usefulness.

**Table 4.** Summation of perceived usefulness

<b>Question (Theme: Perceived usefulness)</b>	<b>Strongly disagree (1)</b>	<b>Disagree (2)</b>	<b>Neutral (3)</b>	<b>Agree (4)</b>	<b>Strongly agree (5)</b>
The fact that a DMS does what it promises to achieve is the most important factor to consider when deciding whether to accept and adopt new technology.	13	31	21	65	56
Usefulness of a DMS means that it will make the job less difficult to do.	13	23	35	62	53
Usefulness of a system strongly influences how employees perceive it	17	26	30	60	53
Usefulness can only be measured by whether the system makes important performance improvements for clients of the service.	10	9	11	105	51
Thereal usefulness of a system can only be determined after it has been fully implemented.	11	7	16	112	40

## 5.5. Satisfaction and enjoyment

Apart from an assessment of the appropriateness of a system to the task at hand, the researcher carried out a specific

evaluation of the role that satisfaction and enjoyment of the system had on decisions on whether to use it. A detailed analysis of areas included in this theme is provided in the table below.

**Table 5.** Satisfaction and enjoyment

Question (Theme: Satisfaction and Enjoyment)	Strongly disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly agree (5)
My satisfaction in using a DMS will influence my support of its continued use.	21	30	42	54	39
Satisfaction and enjoyment of using a DMS have limited or insignificant influence in determining whether or not the system will be consistently utilised.	20	41	30	60	35
User satisfaction is primarily a result of how well the DMS performs identified job-tasks.	14	20	29	73	50
Large workstations will have limited influence in determining my satisfaction and enjoyment	16	40	50	48	32
The ergonomic design will play a huge role in my continued utilisation of the DMS	12	30	40	70	34

According to the feedback received, 46% (n=86) of the participants in the study perceived satisfaction in using a DMS as a highly influential factor. The respondents also believed that user satisfaction with the system was related to higher system performance, which was reflected in survey findings. Specifically, 152 (81%) of the

participants believed that the more satisfactory and enjoyable their experience was in using a DMS, the more likely they were to perform well. The following table offers an item-by-item summary of the responses obtained regarding subjective norms.

**Table 6.** Responses on subjective norms

<b>Question (Theme: Subjective Norms)</b>	<b>Strongly disagree(1)</b>	<b>Disagree(2)</b>	<b>Neutral(3)</b>	<b>Agree(4)</b>	<b>Strongly agree(5)</b>
My peers' opinions about the newly introduced DMS influence my own motivation towards using it.	30	41	52	43	20
Industry reputation as it relates to a DMS influences my willingness to accept and adopt it.	30	58	36	29	33
My decision(s) about whether to utilise a newly introduced DMS are entirely based on my own self-assessment of benefits with little influence from others.	14	21	30	64	42
The reputation of the DMS held by senior colleagues is an important influence in my own beliefs about the system.	20	39	55	41	42
Locally developed DMS can deliver an equally efficient service than those developed in more developed countries in the northern hemisphere.	32	42	42	42	42

In summary, respondents believed that the opinions of their peers, both at the same level and those who were superior, had a significant impact on their motivation to adopt a new DMS.

Behavioural control, as introduced by Azjen (1988) in his theory of planned behavior, is explained in the table below.

**Table 7.** Responses on behavioural control

Question (Theme: Behavioural Control)	Strongly disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly agree (5)
It is important for me to be able to contribute to the development of a DMS as an intended user.	16	33	30	61	46
Being involved in the development and regular evaluation of a DMS provides important motivation to me to accept and adopt it.	20	35	23	50	58
Development of a DMS is for IT experts and there is no need for my involvement as a potential user.	16	30	54	50	36
Being asked to adopt a DMS that was decided on by my management without my involvement negatively influences my motivation to use the system.	14	25	60	59	28
The most important contributors for determining the design of an intended DMS must be the potential users rather than the IT developers.	28	13	43	64	38

In the context of the study, the construct of Perceived Security was investigated using the TAM framework. It was found that a significant number of respondents (74%, n = 137) believed that they should play a

contributory role in the development of the particular DMS as intended users, emphasizing the importance of Perceived Security in the adoption and usage of new technology.

**Table 8.** Responses on perceived security

<b>Question (Theme: Perceived Security)</b>	<b>Strongly disagree (1)</b>	<b>Disagree (2)</b>	<b>Neutral (3)</b>	<b>Agree (4)</b>	<b>Strongly agree (5)</b>
The assessed security of a DMS is of paramount and critical importance in deciding whether to accept and/or adopt it.	17	25	23	69	52
As an end-user, the security of a DMS is not my concern but rather, that of senior management who decided on its procurement.	30	60	70	14	12
System security is primarily related to system-user behaviour's and can be individually determined by different users.	16	40	53	41	36
Security concerns of a system should be balanced against potential usefulness of the system in achieving performance requirements.	10	22	36	63	66
Systems with limited security but high usefulness can be adopted with precautionary measures e.g. using an Electronic –DMS (EDMS) with a paper-based alternative to protect against potential security shortcomings of the newly introduced EDMS	8	14	57	56	51

Categorically, 77% of the participants (n=144) stated that security is of critical importance and agreed with the statement. Perceived risk is an important construct in the Technology Acceptance Model as it

relates to the potential negative consequences of adopting a new technology. The table below summarizes the responses from participants regarding their perceived risks associated with the new DMS.

**Table 9.** Assessing perceived risk

Question (Theme: Perceived Risk)	Strongly disagree(1)	Disagree(2)	Neutral(3)	Agree(4)	Strongly agree(5)
New technology always poses more risks than any comparable existing systems.	32	41	43	43	27
Perceived risk is the single most important reason for not utilising a newly suggested DMS.	22	33	35	60	36
My assessment of a system's risk is influenced by the views of peers	43	60	39	30	14
Perceived risk of a system can be locally managed by training potential users to be more security literate.	10	19	31	72	54
Assessment of a system's risk should be undertaken by strategic managers who procure new DMS and is not a concern for potential users.	17	22	58	51	38

Of the 186 respondents, 131 (70%) agreed with the statement that perceived risk is the most significant factor for not using a new DMS. Perceived compatibility is a measure of how relevant individuals perceive the

technology to be to their job. The table below shows the responses of the respondents regarding four domains related to perceived compatibility.

**Table 10.** Perceived compatibility

<b>Question (Theme: Perceived Compatibility)</b>	<b>Strongly disagree(1)</b>	<b>Disagree(2)</b>	<b>Neutral(3)</b>	<b>Agree(4)</b>	<b>Strongly agree(5)</b>
Compatibility between DMS capabilities and the requirements of the service are a critical deciding factor in my decision to take / accept and/or adopt a new technology.	9	24	28	79	46
Determinations about a DMS are outside the locus of control of end-point users and do not play a role on an individual's motivation to use a newly introduced system.	8	22	60	57	39
End-point users of a DMS do not possess the in-depth expertise about a system to make accurate judgments about its compatibility with the job requirements.	13	30	32	66	45
Compatibility of a DMS with the job requirements can be assessed after an agreed trial period (e.g. of 6 months) and I am willing to fully utilise the system in its trial period even if it means duplicating systems with the pre-existing alternative(s).	19	33	43	49	42

A significant number of respondents, 153 (n=82%), strongly agreed, agreed or were neutral to the posited statement that there must be alignment between the DMS capabilities and the relevance of their job.

Individual mobility:

TAM has undergone numerous modifications and extensions in order to

include additional variables to facilitate its ever-increasing predictive power. Technologies have increased mobility of human interactions both in social spheres and professional domains. The table below presents the four domains in relation to individual mobility, incorporating the participants' responses.

**Table 11.** Individual mobility

Question (Theme: Individual Mobility)	Strongly disagree(1)	Disagree(2)	Neutral(3)	Agree(4)	Strongly agree(5)
The ability for me to personally customise my user functionalities plays an important role in influencing my decision(s) to accept and/or adopt a DMS.	29	54	39	47	17
Systems that allow individual customisation to provide more efficient performance with regard to core job expectations.	20	40	29	54	43
Being able to customise my functionalities is not a necessary pre-requisite to me using a system.	17	35	40	55	39
Flexibility of a system is one of the most important aspects that influence my motivation to accept and/or use it.	12	14	10	77	73

With regard to personal customisation of user functionalities in relation to acceptance or adoption of the DMS, 67% (n= 122) of the respondents were neutral, disagreed or strongly disagreed, while 55% (n=103) affirmed their stance with the statement.

Personal innovativeness is potentially crucial and a significant driver in the adoption and

acceptance of new technological innovations. The following table comprises the participants' responses with regard to personal innovativeness.

There appears to be a stalemate from respondents with regard newly introduced systems being at the “cutting edge” of technology.

**6. Overview of key findings**

The responses from the online survey were in agreement with the general themes that emerged from the individual interviews and the focus group discussions. Importantly, themes were statistically substantiated by

virtue of the fact that the survey had statistically significant representation with 186 respondents. In summation, findings identified offered a basis for the development of theory on what factors have noteworthy influence in document management system choice.

**Table 12.** Responses to personal innovativeness (Source: Author’s own, 2019)

<b>Question (Theme: Personal Innovativeness)</b>	<b>Stronglydisagree(1)</b>	<b>Disagree(2)</b>	<b>Neutral(3)</b>	<b>Agree(4)</b>	<b>Stronglyagree(5)</b>
I believe that any newlyintroduced system should be atthe “cutting edge” of innovationand should surpass systemsutilised by similar serviceproviders.	23	40	58	33	32
Innovativenessis notasimportant to me as the system’sability to perform to identifiedwork and taskexpectations.	18	27	40	52	49
The future of documentmanagemen t systems will be IT-based, and it is important that allinnovative approaches make useofthat aboveall.	16	30	35	60	45
The security risks associatedwith using innovative IT DMSoptions are a minorconsideration and should not bethe basis for decision whether ornot a new system should beintroduced.	31	45	50	34	26

### 7. Recommendations

The recommendations borne out of the findings can contribute substantially towards a more in-depth and incremental understanding towards the successful implementation and adoption of a customised, purpose-built document management system for the public sectors. The eThekweni Municipality has no doubt made and is making huge strides in trying to provide basic services to the citizenry, but the opportunity to embrace technologies increasingly in their strategic endeavors will go a long way in better servicing the community. The time is now.

### 8. Conclusions

The current study adopted and embraced the exploratory sequential mixed method design as this was best suited to answering the key

objectives. Data analysis, presentation, and interpretation was then expounded, and this ultimately culminated in the proposed framework being developed. The model is so designed that further testing will facilitate a better understanding of the technology acceptance behaviors and also contributes to the understanding of the dynamic nature of the technology acceptance process. The recent surge in technology in creating competitive advantages are at the vanguard of opportunity, but as we note almost daily, it is a formidable challenge for management and organizations. The degree of technocratization and enabling a facilitating environment is a huge challenge for public sectors. However, with a concerted effort, strategic orientation, and armed with a better understanding of the factors that contribute to successful implementation and adoption of technology, the level of success is raised.

## **INDEX SCALE OF TOTAL QUALITY MANAGEMENT IMPLEMENTATION ON THE PERFORMANCE OF MSMEs PRODUCERS OF GRC**

***Abstract:** MSME Manufacturing sector is always interesting to research, for this reason, this research will be carried out in MSMEs in the GRC manufacturing sector in the East Jakarta and West Bekasi areas. This study aims to develop a study on the application of the Total Quality Management (TQM) method that has been implemented on SMEs, precisely to find out what percentage of TQM implementation that has been implemented in product quality control and improvement as well as to propose an alternative quality management system that is better for using TQM approach. This study uses a qualitative descriptive approach that combines direct observation in the field with literature studies from previous studies. As a basis for discussion, the authors use the basic concepts of TQM that have been developed by experts, which the authors modify for the purposes of this study. The results showed that the application of TQM principles to MSMEs had only reached about 60% of the ideal target which should have been 100%. There needs to be serious efforts and support so that MSMEs are able to fully TQM in order to improve the performance of MSMEs as a whole.*

***Keywords:** MSMEs, TQM, Improve, Performance*

### **1. Introduction**

Deputy for Business Restructuring of the Ministry of Cooperatives and Micro, Small and Medium Enterprises (MSMEs)), Eddy Satriya at the Scale Up With Whatsapp event, on Tuesday, 7/21/2020 stated that currently there are around 64.19 million MSMEs or 99.9% of the total business units in Indonesia with a contribution of 97% (employment), 60% (national GDP), 58% (national investment), 14% (national exports) (Arizal et al., 2021). This shows that small and medium enterprises are the foundation of the Indonesian economy,

which absorbs a lot of labor, but their performance needs to be continuously developed (Fadilurrahman et al., 2021).

SMEs in the manufacturing sector, especially the business of making Glass Reinforced Concrete (GRC) or also known as Glass Fiber Reinforced Concrete (GFRC) is one of MSMEs businesses that is interesting to study because its products are widely used in construction projects today (Habibah et al., 2021). For this reason, this research will be carried out in SMEs in the GRC manufacturing sector in the East Jakarta and West Bekasi areas where this location is one of the centers for GRC

Corresponding author: Eka Rakhmat Kabul  
Email: [eka.rakhmat@upi-yai.ac.id](mailto:eka.rakhmat@upi-yai.ac.id)

manufacturing in Indonesia, especially DKI Jakarta (Handayani et al., 2022).

This study aims to develop a study on the application of the Total Quality Management (TQM) method that has been implemented on MSMEs, precisely to find out what percentage of TQM implementation that has been implemented in product quality control and improvement as well as to propose an alternative quality management system that is better for using TQM approach (Hidayat et al., 2021).

Descriptive qualitative methods will be the approach in this study where the discussion is focused on determining alternatives to improve quality management. Leaders and employees of 4 MSMEs in the GRC manufacturing sector will be the main informants of the research in addition to direct observations on processes in the field, document studies and discussions with experts (Irpan et al., 2021).

There have been many studies on the application of TQM to MSMEs, but no one has explicitly stated what percentage of TQM applications are to MSMEs, only almost all studies conclude that the application of TQM has a positive effect on company performance. For this reason, it is necessary to further deepen the extent to which the application of TQM has a positive effect on company performance and what recommendations should be given to MSMEs when they implement TQM in their companies.

The paper is to be written in two-column format. Paper size should be 19cm width and 26cm height. Text should be right and left justified, using single spacing (Times New Roman 10 pt) and 3pt spacing after each paragraph. The width of top margin is 2.85cm, left 2.5cm, right is 3cm, and bottom margin is to be 3cm. The width of each column is to be 6.4cm, and the gap between columns should be 0.7cm.

## **2. Literature review**

### **2.1. Micro, Small and Medium Enterprises (MSMEs)**

In general, the definition of MSMEs is a trading business managed by individuals or business entities and in accordance with the criteria for small or micro businesses (Iyansyah et al., 2021). So, in accordance with the definition of MSMEs, the criteria for MSMEs are distinguished individually, which include micro, small and medium enterprises. In addition to this classification, the government hopes that MSMEs can play a role in building the national economy, including the development of regional potential-based and market-oriented businesses (Kusuma et al., 2016; Joko et al., 2022). So, so that you understand more about the meaning of MSMEs, just take a look at the following reviews that have been reported from various sources (Mahfuzah et al., 2021; Kurniawan et al., 2021). Government Regulation No. 7 of 2021 concerning the Ease, Protection, and Empowerment of Cooperatives and Micro, Small and Medium Enterprises has been issued by the government along with 48 other implementing regulations from Law No. 11 of 2020 concerning Job Creation (UU Cipta Kerja) on 16 February 2021 (Norrahmi et al., 2021). The government regulations changed several provisions that had previously been regulated in Law no. 20 of 2008 concerning Micro, Small and Medium Enterprises (UU UMKM) (Norrahmiati et al., 2022). One of them is the rules related to the criteria for SMEs themselves. MSMEs are grouped based on the criteria for working capital or annual sales results (Putera et al., 2022). The criteria for working capital are used for the establishment or registration of MSME activities established after the government regulation comes into effect (Ramadhani et al., 2021). So now the stipulation is that Micro Business has a

business capital of up to a maximum of Rp. 1,000,000,000.00 (one billion rupiah) excluding land and building for business premises, Small Business has a business capital of more than Rp. 1,000,000,000.00 (one billion rupiah) up to a maximum of Rp. 5,000,000,000.00 (five billion rupiah) excluding land and buildings for business premises and Medium Enterprises have a business capital of more than Rp.5,000,000,000.00 (five billion rupiah) up to a maximum of Rp.10,000,000,000.00 (ten billion rupiah) excluding land and buildings for business premises.

## 2.2. The Basic Concept of TQM

Total Quality Management (TQM) is basically a quality management system that focuses on the customer aspect (customer focused), by involving all employees at various levels within the company to make continuous improvements (Rizal et al., 2021). Total Quality Management is essentially the continuous improvement of people, processes, products (including services), and the environment. With total quality anything and everything that affects quality is a target for continuous improvement. When the concept of total quality is applied effectively, the end result can include organizational excellence, superior value, and global competitiveness (Goetsch & Davis, 2014; Rahmadani et al., 2021). Improve customer satisfaction and other stakeholders through effective goal dissemination, cost reduction, process improvement, people involvement, and supply chain development has proven essential for organizations to exist in the 21st century, TQM is a way of managing the future because if you ignore products and quality of service can have disastrous consequences, damage to a company's reputation has consequences deeper and faster than ever before as information, opinions and ultimately consumer choices,

are affected by the scale and nature of modern communication technology and of course, TQM is much broader in its application than ensure the quality of a product or service, it is a way of managing an organization to improve every aspect of performance, either internally and externally (Oakland, 2014).

TQM implementation areas, such as supplier relations, benchmarking, commitment top management, and customer focus are critical factors in quality management (Rizani et al., 2022). Some researchers found a relationship that top management commitment, customer focus, satisfaction customers, human resource management, training, and education is the most important TQM practice for manufacturing and service companies (Saputra et al., 2022). Process management and commitment top management represents the elements of TQM with influence the biggest on organizational performance in the industry (Aziz, 2019).

There are many basic concepts of TQM that have been put forward by experts which we can synthesize that TQM is basically customer-focused quality management, carried out by all elements of the organization and carried out continuously and efficiently (Shaddiq et al., 2021).

## 2.3. TQM Implementation on MSMEs

Until now, large companies still dominate the discussion about TQM and the continuous improvement process, this is in contrast to small and medium enterprises which have not paid much attention to the implementation of TQM even though MSMEs are one of the pillars of a country's economy (Surti et al., 2022). In fact, large companies that have used TQM establish business relationships with MSMEs as distributors of raw materials or other services, this forces MSMEs to meet a number of quality standards in order to

support the successful implementation of TQM in large companies (Wagiono et al., 2022).

The application of TQM can increase the competitiveness of SMEs through long-term commitment, continuous improvement, education & training and unity of purpose. All of this is the responsibility of top management because the success of TQM in MSMEs is strongly influenced by the awareness of top management which will have a direct impact on the overall performance of the company (Sari & Firdaus, 2018).

TQM is significant on managerial performance and has no effect on profits, but in other studies it is stated that the application of TQM in the company will increase company profits, is a human resource issue (Ch & Aji, 2020).

The level of implementation of traditional MSME quality management is still low because TQM has only been carried out in the production aspect with the trend of production volume and the number of customers increasing, increasing production volume by increasing human resources and company management in order to obtain optimal revenue (Bremanti, Hubeis & Palupi, 2018).

Of the many studies on the application of TQM in MSMEs, the three research results above can represent all of them, which in essence is the application of TQM in MSMEs has given good results even though

the level of application is different so the results are different. Further studies are needed that can provide recommendations on how TQM should be carried out in MSMEs). For this reason, the research will be deepened again how the level of application of TQM in MSMEs so that later it can provide recommendations for the application of TQM to similar MSMEs and in situations and conditions similar to the object of this research (Wijaya et al., 2021). Literature review is the survey of scholarly sources on a specific topic. It analyzes and synthesizes and critically evaluate to give a clear picture of the state knowledge on the subject.

### 3. Method

This study uses a qualitative descriptive approach that combines direct observation in the field with literature studies from previous studies within a maximum period of 5 years on a national and international scale in order to obtain a connecting line between this research and previous research. The literature study used is research that has been published through digital searches with online-based academic index media. As a basis for discussion, the authors use the basic concepts of TQM that have been developed by experts, which the authors modify for the purposes of this study.

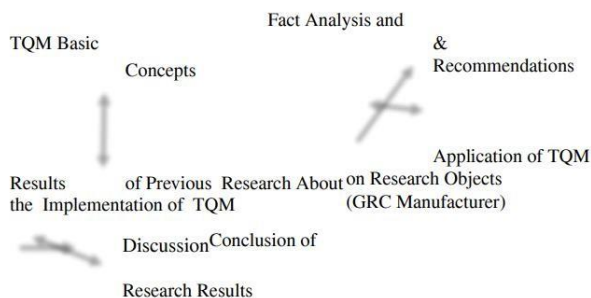

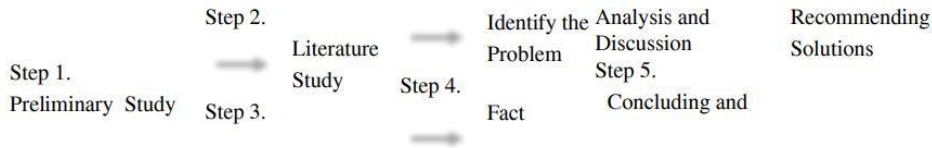

Figure 1. Research Thinking Framework

Based on the research framework in Figure 1 above, the steps involved in conducting this

research are as follows:

**Figure 2.** Research Thinking Framework

**Step 1. Preliminary Study:** to find out the extent of the implementation of TQM in MSMEs in 4 MSMEs that produce GRC to obtain the information needed for the next stages of research, carried out by direct observation of all processes regarding the products they produce, namely GRC starting from implementation tender, supplier selection, production process, distribution to consumers and installation of GRC in places that have been determined by consumers.

**Step 2. Literature Study:** This is done in order to better understand the technical problems faced, in this case are scientific journals related to the application of TQM as well as TQM theory books and other fields of science that are relevant to the problems at hand so that they can support problem solving.

**Step 3. Problem Identification:** carried out by observing directly in the field and also interviews with related MSME actors to find out how far the effectiveness of the application of TQM on MSMEs in improving product quality that aims to meet customer satisfaction, where there are several main problems that must be corrected from each process. All processes that have been observed will be compared with previous literature studies.

**Step 4. Fact Analysis and Discussion:** after direct observations and interviews with MSME actors are carried out, the next step is to analyze the information and facts obtained. The analysis carried out is by using the Total Quality Management method approach and then a discussion of the results

of the analysis is carried out.

**Step 5. Concluding and Recommending Solutions:** after the research stages have been carried out as a whole, conclusions will be drawn on all these stages in accordance with the research objectives that have been set and then provide recommendations in the form of proposals as useful contributions.

## 4. Results and discussion

### 4.1. Results

Field observations and interviews were conducted based on the research focus which consisted of 6 key elements of TQM which the authors developed into 19 observations and interview questions as a sub-focus of the research. the results of direct observations and interviews will then be given an assessment. The values obtained are then compared with the theory of TQM principles. In order to facilitate the analysis and understanding, the researchers grouped the results of the analysis into a value scale as shown in the following table:

**Table 1.** TQM Process Ideal Value Scale

Score	Implementation Percentage
1	1% – 20%
2	21% - 40%
3	41% - 60%
4	61% - 80%
5	81% - 100%

Source: Processed data (researcher provisions), 2021

#### 4.2. Discussion

Based on study results, the average score is 3 (rounded score of 3.26), and if based on the scale of the ideal value of the TQM process in table 1, it means that the application of TQM principles in MSMEs has only reached about 60% of the ideal target which should be 100%. From the table of observations, it can be seen in what parts the low value is 2, which means that it has only been applied around 21% - 40%, namely. That is in the context of question Number 13: Are MSMEs ready to release the root cause of the problem or do you just firefight over the symptoms?

Things that weaken these aspects are:

1. Lack of Customer Focus: Quality leadership requires a focus on the customer. This means that the main goal of the organization is to meet or exceed customer expectations through something that provides lasting value to customers, both internal and external customers.
2. Lack of Obsession with Quality: Lack of obsession with quality greatly affects employees regarding the achievement of quality in order to exceed the expectations of internal and external customers.
3. Lack of Understanding of Work Structure: The work process should be further analyzed to determine the appropriate structure arrangement (organization, work order SOP (Standard Operation Procedure), tools used, and others). When the optimum structure has been achieved, the work process must be analyzed, evaluated, and studied continuously in order to improve it.
4. Uncontrolled Freedom: Control in the sense of TQM is human control of work methods and processes.

Leaders must ensure that managers and employees control work processes and methods by standardizing them together. The goal is to reduce variations in output by reducing variations in work processes.

5. Lack of Unity of Purpose: In this case, a leader is responsible for determining and conveying the organization's mission clearly and carefully so that all employees understand, believe, and are responsible for the mission. With the unity of purpose, all employees work related to the system.
6. Likes to find system errors: In order to prevent employees' liking for system errors, it is necessary to change the focus or emphasis on error assessment due to a problem becoming a system assessment in order to find and analyze problems related to the system.
7. Lack of Teamwork: In order for strong teamwork, a principle must be needed, which is based on the belief that working together will be able to give much better results than working individually.
8. Lack of Continuing Education and Training: Continuous education and training in the technological era is very necessary because the most important machine in the work environment is the human mind. Therefore, continuous learning is a fundamental element in TQM.

#### 5. Conclusion

Based on the introduction, problem identification, findings and research analysis described above, the conclusions in this study are as follows:

1. This research produces some information about the process carried out by MSMEs

starting from the tender process, production, distribution to product installation at consumer locations. Information obtained through direct field observations and interviews with GRC production managers obtained complete information about the processes that occur starting from the GRC production project tender process followed by the production scheduling process, raw material purchasing, production process, tidying process, distribution and installation process of GRC products. the place specified by the customer and after-sales service.

2. The results showed several management methods as tools used by MSMEs to control and improve product quality and quality. Based on the data from the research conducted, it was found that MSMEs have not fully applied the TQM method 100% but have only applied about 60%, so there are still some MSME potentials that have not been explored and utilized optimally for the advancement of MSMEs.

3. From the results of the research that the researchers plotted into the analysis table, it was found that the values of the process stages could be improved and improved. These stages can be seen from a technical point of view as well as from a management perspective. The TQM method describes several methods or good ways to improve performance. With the application of this method, it is hoped that better MSME performance will be obtained.

Suggestions/recommendations that researchers can convey based on the results of this study are:

1. That the TQM method if applied seriously and seriously, will be able to improve the quality and quality of the product. Through overall quality management and the responsibility for product quality is not only borne by the Quality Control department, but all parts of the organization have the same responsibility so that it is hoped that

product quality will be maintained and the overall performance of MSMEs will increase.

2. The theory of TQM principles does not absolutely have to be done directly and carried out in a short time. But it would be nice to implement TQM principles in stages and start from the smallest and simplest things. The implementation of TQM principles must also be adapted to the existing conditions of MSMEs.

3. MSMEs should apply the TQM method in carrying out all their operational activities, because applying the TQM method as a whole is expected to increase work efficiency and is expected to improve the overall performance of MSMEs.

4. For further researchers, it is recommended that they research on different objects and expand the sub-focus of the research so that more comprehensive and in-depth research can be produced.

## HOW DO TQM PRACTICES AFFECT EMPLOYEE EFFECTIVENESS IN TUNISIAN SMEs?

**Abstract:** Total Quality Management (TQM) is a key strategy used by human resources to maintain a competitive advantage. Indeed, TQM is essentially based on the strategy and culture of the company as well as on the maturity and awareness of the managers. Therefore, TQM has a strong relationship with Employee Effectiveness to ensure the improvement of all company performance. Thus, the purpose of this study is to show the nature of the relationship between TQM and employee effectiveness and to judge whether TQM affects employee effectiveness or not. In this context, we have used the survey method to study the behavior of Tunisian companies. 206 responses were collected and analyzed using the software "SPSS". Then, structural equation modeling was used to validate the work's hypotheses. The obtained results show that TQM has a positive impact on employee effectiveness and that all TQM practices affect positively employee effectiveness.

**Keywords:** Total quality management, Employee effectiveness, SEM; Empirical research.

### 1. Introduction

Total Quality Management (TQM) is a management philosophy that focuses on the continuous improvement of products, services, and processes to meet or exceed customer expectations (Banuro et al., 2017). It encourages employees to take ownership of their work and to participate in continuous improvement efforts. This can lead to increased job satisfaction, motivation, and engagement, which in turn can lead to higher levels of productivity and performance.

TQM also emphasizes the importance of training and development, which can help employees acquire new skills and knowledge and improve their effectiveness on the job. By investing in employee development, organizations can create a culture of

continuous learning and improvement.

Another key aspect of TQM is teamwork and collaboration. By working together to identify and solve problems, employees can build stronger relationships and improve communication and coordination. This can lead to a more efficient and effective workplace, as well as higher levels of job satisfaction and engagement.

In this context, TQM start to be adopted in Tunisia, especially in manufacturing companies, as a means of enhancing efficiency and competitiveness. However, there can be a problem between employee effectiveness and TQM implementation in Tunisia. This is because some employees may resist the changes that come with TQM implementation. They may feel threatened by the changes or may not understand the

Email: [ala.zouari@isgis.usf.tn](mailto:ala.zouari@isgis.usf.tn)

need for them, leading to a lack of commitment to TQM initiatives. Another issue is the lack of effective communication and training on TQM principles and methods, which can make it difficult for employees to understand their role in the implementation process. In addition, there may be cultural barriers that need to be addressed to successfully implement TQM in Tunisia, such as a reluctance to question authority or challenge established ways of doing things.

Companies that seek to enhance their chances of survival have implemented TQM practices, which prioritize quality and continuous improvement as part of their strategic objectives. These practices involve utilizing management concepts and tools to engage both managers and employees in the pursuit of ongoing performance enhancement. Success factors and TQM practices have been identified by numerous authors (Alawag et al., 2023; Hchaichi, 2023). Lehyani et al. (2018) have identified the six most crucial TQM practices in scientific literature which are: leadership, customer focus, Human Resources Management (HRM), process management, information analysis, and continuous improvement.

In this framework, Lehyani et al. (2022) have studied the application of TQM practices in Tunisia. The results indicate that over 90% of SMEs in the "Petrochemical," "Manufacturing," "Agri-food," and "Textile" sectors apply TQM, while only SMEs in the "Construction" sector apply TQM at a rate between 80 and 90%. Furthermore, between 70 and 80% of SMEs in the "Electric & Electronic," "Telecommunication," "Automotive," and "Service" sectors responded positively to the application of TQM. SMEs in the "Transportation & Distribution" and "Materials" fields responded equally with 66.7%, while those in the "Training" and "Healthcare" sectors had an equal rate of 50%. Furthermore, in

the first category, all TQMP practices, except "Information analysis", are frequently applied in more than 70% of cases in the "Materials" and "Agri-food" sectors. In the "Training" field, only "Leadership" has a 66.67% application rate. Similarly, in the "Textile" sector, only "Customer focus" and "HRM" have a 66.67% application rate. Among the industrial domains, the "Telecommunication" sector had the highest rate of TQMP application, with three practices applied commonly in more than 70% of cases, and two practices, "Customer focus" and "Process management," applied in 62.5% of cases.

Based on related works such as (Israfilov et al., 2020; Rombaut & Guerry, 2020; Enenifa & Akintokunbo, 2020) The employee effectiveness practices are: employee expertise, continuous employee learning, employee involvement & commitment, integration/ interaction with employees, employee performance, use of technological resources.

The impact of TQM on employee effectiveness has been widely studied in many countries. In this vein, Khan et al., (2019) have found that TQM practices positively influenced employee job satisfaction, which in turn positively influenced employee creativity and proactive behaviors. In addition, Ali et al., 2020 have claimed that TQM practices positively influenced employee job satisfaction, organizational commitment, and employee performance. Moreover, Ababneh (2021) has affirmed that TQM practices positively influenced employee job satisfaction and employee engagement, which in turn positively influenced employee performance. Also, Galeazzo et al., (2021) have argued that TQM practices positively influenced employee job satisfaction, employee commitment, and employee performance, and that employee involvement in TQM activities was a significant mediator in these relationships. Regarding healthcare field,

Dagasan et al. (2023) pointed out that TQM principles produce different performance outcomes like the job performance of employees. Furthermore, Lehyani et al. (2023) studied the impact of knowledge management and TQM impact on employee effectiveness in Emerging Industries in the case of Tunisian Small and Medium enterprises (SMEs) and they confirmed that there is a positive and significant relation between TQM practices application and employee effectiveness determinants.

In summary, it is remarkable that TQM and staff effectiveness have mutual relationships based on the intersection of their practices. Hence, the aim of this research is to answer the following question: is there an impact between TQM and employee effectiveness in Tunisian companies?

In this circumstance, the aim of this study is to investigate the feasibility of implementing TQM practices in small and medium-sized Tunisian enterprises, and to determine their impact on the effectiveness of employees. To achieve this objective, the survey method was employed and the data gathered were analyzed using SPSS software. Then, the Principal Component Analysis (PCA) method was used and the hypotheses of the model were validated by applying the SEM method. Thus, the significance of this research lies in its examination of the relevance of TQM practices in the context of Tunisian SMEs and their potential effects on employee effectiveness.

## 2. Research methodology

### 2.1. Data collection method and Measurement instrument

This work is based on a survey designed to study TQM's impact on staff effectiveness in Tunisian SMEs. The survey was divided into two sections. Section 1 contains questions related to the descriptive details of

enterprises. Section 2 consists of open-ended questions that respondents can answer using a Likert scale ranging from 1 to 5, from very low impact to very high impact.

The survey was distributed in two ways: direct contact with 125 companies and sending emails to approximately 3000 companies from several fields. With this strategy, the percentage of responses obtained by direct contact is around 80%, and by sending emails is about 3.5%. Hence, the total number of obtained responses was 206. However, questionnaire validation was carried out by academic and non-academic experts who checked the nature of the questions, their understanding, consistency, etc. The instrument had a Cronbach's Alpha of 0.986, which is considered reliable (Azizi et al., 2016). Indeed, survey questions were coded to be processed by "SPSS" software version 24.

### 2.2. Reliability

For Gandhare et al. (2018), reliability analysis is a correlation-based procedure estimated using the Chronbach Alpha " $\alpha$ " reliability coefficient. This coefficient varies between 0.00 and 1.00 and its generally acceptable minimum value is 0.7. Similarly, Katiyar et al. (2018) assert that the acceptable reliability of the indicators must exceed the recommended threshold of 0.70. However, Zaied et al. (2012) states that if the test shows that the  $\alpha$  value is equal to or greater than 0.80, this means that the collected data are consistent.

### 2.3. Validity

Convergent Validity is assessed using Item Loading, Composite Reliability (CR), and Average Variance Extracted (AVE). To accept convergent validity, the values of all these measurements must be greater than 0.5. In contrast, Lu et al. (2019) argue that the CR and AVE are adopted to measure

convergent validity and that the CR must be greater than 0.7 and the AVE must be greater than 0.5. However, the discriminant validity specifies to what extent a given construction is different from all other constructions of the same measurement model. It can be examined by comparing values with the diagonal square root of the AVE with correlations between reflective constructions (Katiyar et al., 2018).

## **2.4. Exploratory Factor Analysis**

Exploratory Factor Analysis (EFA) is performed using the maximum probability of rotation "Varimax" to verify that validity and reliability criteria of variables are satisfactory and correlated (Singh et al., 2018). According to Qasrawi et al. (2017), for the AFE to be carried out, the data must satisfy the following conditions: 1) Kaiser-Meyer-Olkin (KMO) measurement must be greater than 0.5. 2) the eigenvalue of each factor must be at least 1. 3) a minimum load factor of 0.40 for the preservation of each element must be achieved. For our empirical study, we chose the PCA method to verify the validity of the factor adjustment test since it provides the correlation between the factors with the unique variance of the elements.

## **2.5. Confirmatory Factor Analysis**

For the model to be accepted and sampling to be adequate, KMO must be greater than 0.6 (Singh et al., 2018). However, Bartlett's sphericity test is significant if  $p=0.00$  (i.e. the null hypothesis of the correlation matrix being an identity matrix must be rejected). In this case, the sample can reduce the factors and is suitable for factor analysis (Qasrawi et al., 2017).

After the exploratory analyses are performed, Confirmatory Factor Analyses (CFA) are used to define and represent one

or more hypothetical models of factor structure. Each suggests a set of unobserved variables to account for covariance in a set of observed variables (Zhang & Min, 2022). Depending on Dissanayake & Cross (2018), Structural Equation Modeling (SEM) follows certain hypotheses of statistical distribution, since it is assumed that the observations are independent of each other and that the exogenous variables have a multivariate normal distribution. Indeed, several adjustment indices are considered to judge the adequacy of the model. In our case, our model was assessed by examining the goodness-of-fit statistics indices: ratio of  $\chi^2$  to degree of freedom, Root Mean Square Error of Approximation (RMSEA), Parsimony Goodness of Fit Index (PGFI), Akaike's Information Criterion (CAIC), Parsimony Normed Fit Index (PNFI), and Comparative Fit Index (CFI).

## **2.6. Structural Equation Modeling**

In order to test the causal links between KM elements, TQM factors, personnel effectiveness practices and SCP dimensions, we applied the SEM. This method is a methodological approach that tests complex causality models incorporating latent variables. The set of causal relationships between latent, dependent and independent variables of our model compose our study hypotheses. The method application will be developed by the software AMOS 24 and the method that will be used for the data estimation is the Maximum Likelihood (ML) method.

# **3. Results and discussions**

## **3.1. Sample demographics**

A summary of the participating companies and respondents is presented in Table 1.

**Table 1.** Summary of participated companies and respondents

Relevant Dimension	Profiles in percentages	Relevant Dimension	Profiles in percentages
Localisation	37.4% Sfax	Activity field	18.9% Service
	17% Tunis		5.8% Petro-chemical industry
	7.3% Nabeul		6.8% Electric & Electronic
	4.4% Ariana		2.9% Training
	4.9% Ben arous		1.9% Health
	4.9% Sousse		7.8% Construction
	4.4% Mahdia		5.8% Transport & distribution
	3.4% Bizerte		17% Agri-Food
	3.4% Monastir		5.3% Automotive
	2.9% Gabes		13.6% Manufacturing
	2.4% Medenine		5.8% Textile
	2.4% Zaghouan		4.4% Materials
	1% Beja		3.9% Telecommunication
	1% Jendouba		15.5% less than 9
	0.5% Gafsa		25.7% between 10 and 49
	0.5% Kairouan		26.7% between 50 and 249
	1.5% Manouba		32% More than 250
0.5% Sidi bouzid	24.8% Quality Manager		
0.5% Tataouine	17.5% Human Resources Manager		
Certification	51.5% QMS	Respondent function	16% Logistics Manager
	16.8% EMS		6.8% Production Responsible
	9.9% OHSMS		4.4% Purchasing & Supply Manager
	5% FSMS		6.8% Sales & Marketing Manager
	3% SMS		7.3% Technical Manager
	2% Others		2.9% Financial Officer
	9.9% Not certified		3.4% Administrative Officer
	2% In progress		10.2% General Manager

### 3.2. Exploratory Factor Analysis results

The measurement of KMO and Bartlett sphericity results show that they are well accepted in our analysis, see table 2. Therefore, it can be concluded that the data show a suitability and homogeneity conducive to PCA application.

**Table 2.** KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.894
Bartlett's Test of Sphericity	Approx. Chi-Square	1443.009
	df	66
	Sig.	.000

Based on the results presented in table 3, two factors have been selected, with an eigenvalue greater than 1. These factors provide a cumulative percent variance of 64.78%. The 1st factor provides 51.93% of the total variance and the 2nd factor brings 12.84%. This allowed us to conclude that the mass of information retained by these two factors is quite significant. Then, we calculated the correlations between these factors, the retained measurement variables, the corresponding standardized factor loadings, and t values resulting from testing the items' coefficients in CFA, see table 3.

**3.3. Tests for reliability and validity of the constructs**

Cronbach’s alpha was used to measure the reliability of the multi-item scale to assess internal consistency. Also, it was used to ensure that the scale items are free of measurement errors and that they quantify the corresponding latent variables (Masa'deh et al., 2019). However, structural reliability will not increase significantly if elements are removed from the analysis.

Table 4 exposes descriptive statistics, Cronbach’s alpha values, and variables Pearson correlations in our research model. In this regard, it is noted that the reliability analysis of TQM practices was 0.884 and the reliability analysis of employee efficiency practices was 0.896. According to Wang et al. (2019), if the alpha values of all variables exceed the threshold of 0.70, we can conclude that this is an excellent reliability, which is the case for our work.

**3.4. Test results of the structural model**

The results for the adjustment of the structural model are shown in Table 5. Based on these results, we can conclude that the index values are acceptable and satisfactory and that our structural model shows a good quality of adjustment.

**Table 5.** Results of structural model

Goodness-of fit statistics	Structural model	Recommended values
$\chi^2/df$	2.798	<3
Root mean square error of approximation (RMSEA)	0.094	<0.08
Parsimony goodness-of-fit index (PGFI)	0.612	>0.5
Parsimony normed fit index (PNFI)	0.722	>0.5
Comparative fit index (CFI)	0.933	>0.9
Goodness of Fit Index (GFI)	0.900	>0.8
Adjusted Goodness of Fit Index (AGFI)	0.853	>0.8
Root-mean-square residual (RMR)	0.034	≤0.05

According to Zhang & Min (2022), to support a tested hypothesis, it is necessary to examine the Coefficient Ratio (CR) which should be greater than 1.96. Also, the probability of release of H0 must be less than 0.05 ( $p \leq 0.05$ ). Table 6 presents the path models estimating, direct and indirect effects of TQM practices on employee effectiveness from the structural model. It shows that the model not needs modification to be used for the further analysis and that all the relationships have significant regression weight.

**Table 3.** Rotated factor matrix of the TQM practices and employee effectiveness

	Measure/construct	Factor loadings		Eigenvalue	Percentage variance explained by factor	Percentage total variance explained	t-value
		Component 1	Component 2				
Employee Effectiveness	Employee expertise	-	.793	6.23	51.93	51.93	62.558
	Continuous employee learning	-	.792				58.303
	Employee involvement & commitment	-	.786				61.213

	Integration/ interaction with employees	-	.779				56.017
	Employee performance	-	.775				61.847
	Use of technological resources	-	.678				60.484

## 4. Discussion and study implications

### 4.1. Managerial implications

The proposed model can serve as a valuable tool and strategic plan for managers, allowing them to understand the connections between TQM practices and staff effectiveness. However, the model is not set in stone and can be customized to suit the specific needs of the organization. By utilizing the results obtained from our study, managers can accurately gauge the impact of TQM practices on staff effectiveness and make informed decisions to enhance employee productivity. Furthermore, establishing positive relationships between staff effectiveness and TQM practices can motivate leaders to prioritize the well-being of their employees by fostering a positive work environment and encouraging their active participation in decision-making processes. Ultimately, the commitment of managers to implementing TQM practices and promoting employee effectiveness can directly influence overall employee performance.

### 4.2. Research limitations

Although our study produced noteworthy results, it is important to acknowledge the limitations that need to be addressed in

future research. One of the limitations is the difficulty in obtaining cooperation from industrial managers, which may have influenced the sample size. Furthermore, the number of companies that participated in the study was limited. Additionally, although we collected data from various industrial sectors, we did not perform a sector-specific analysis as the sample size was not representative of most industries. Addressing these limitations could help provide a more comprehensive understanding of the relationship between TQM practices and staff effectiveness in different industries.

### 4.3. Implications for future research

We have identified several potential research directions based on the findings of our study. First, we suggest the use of alternative data collection methods such as direct access to company data to overcome the challenges of confidentiality and to enable the identification and analysis of barriers to TQM implementation in Tunisian companies. This would also allow for an investigation of the reasons behind the application of some TQM elements and staff effectiveness practices while neglecting others. Additionally, we propose conducting a comparative study by disseminating the survey to companies in other developed and/or developing countries. This could provide valuable insights into how TQM

practices and staff effectiveness differ across countries and industries. Overall, these research directions could contribute to a deeper understanding of how TQM practices can be effectively implemented and the factors that contribute to staff effectiveness.

### 5. Conclusion

In this study, the primary objective was to examine the impact of TQM practices on staff effectiveness in Tunisian companies. The results indicate that TQM practices have a positive effect on staff effectiveness, particularly in the areas of leadership, customer focus, human resources management, process management, information analysis, and continuous improvement. The findings suggest that companies that prioritize effective

management approaches are more likely to attain higher levels of employee effectiveness. This can be achieved through evidence-based decision-making, quality programs, and training, as well as creating a motivating and balanced work environment, among other strategies. Based on the findings, it is recommended that managers in Tunisian companies lead by example by sharing their knowledge and experiences with their employees and by adhering to all quality procedures and guidelines established by the company. It is also important for managers to not only focus on what they are paying their employees, but also on what benefits they can provide to them.

## DEVELOPMENT OF A FRAMEWORK FOR DEFINING THE CONCEPT OF QUALITY 4.0

**Abstract:** Industry 4.0, better known as the Fourth Industrial Revolution, is a concept that refers to the application of high technologies, such as the Internet of Things (IoT), cybernetics, machine learning, automation of production and the entire business. This concept aims to improve efficiency, productivity, and flexibility and reduce costs. On the other hand, Quality 4.0 is the integration of smart technologies and digitalization into the manufacturing process to improve quality control and increase efficiency. It involves using IoT devices, machine learning, and big data analytics to monitor and optimize production processes in real time, resulting in reduced defects, increased productivity, and improved product traceability. By using these technologies, manufacturers can reduce the risk of defects and downtime, increase productivity, and improve product traceability. Quality 4.0 is an essential aspect of Industry 4.0. It represents the integration of digital technologies into the quality control process. The main objective is to achieve higher quality products, reduce defects, and optimize production processes using real-time data analytics. This approach emphasizes the importance of data-driven decision-making in manufacturing and highlights the benefits of integrating data analysis into quality control processes. Overall, Quality 4.0 focuses on improving the quality of products and processes using modern technology, resulting in increased efficiency, productivity and flexibility.

**Keywords:** Quality 4.0, Industry 4.0, Quality Management; Competencies, Knowledge Management

### 1. Introduction

The world has experienced three industrial revolutions. The first one, which occurred in the late 1700s and early 1800s, was fueled by innovations in steam and water power, which enabled factories to expand their production capacities and potential locations. Before this, factories were situated near

rivers to harness water wheel energy. Later, the discovery of electric power and infrastructure developments led to the mass production of machines and the expansion of iron ore production. The expansion of railways facilitated the procurement of supplies and delivery of finished products in the US. The widespread availability of energy sparked the development of digital computing, with the emergence of

---

Corresponding author: Jovana Nikolić  
Email: [jovana.nikolic.jag@gmail.com](mailto:jovana.nikolic.jag@gmail.com)

mainframe and client-server computers, the Internet, and e-commerce. The third industrial revolution emerged in the late 1960s with the programmable logic controller, which brought about process automation through the control of tank filling, motor starting and stopping, and sequencing control events.

Just 20 years ago, companies could barely redirect phone calls within departments or sell through websites. Today, it is an integral part of the workday. Mobile devices and cloud computing have led to an expansion of services, as different communication channels (phone, web, tablets) have fully shifted towards customers.

The first industrial revolution was characterized by the invention of steam-powered machinery, followed by the use of electric power and assembly line production in the second. The third industrial revolution saw innovations in computing and industrial automation. The fourth industrial revolution is defined by the integration of machine intelligence, pervasive computing, accessible storage, and robust connectivity. It builds on the foundation of the previous industrial revolution, including digitalization, computer networks, robotics, artificial intelligence, smart machines, smart factories, modelling and simulation, nanotechnology, transportation, and other smart components of development (Zonnenshain&Kenett, 2020). Accompanying Industry 4.0 is Quality 4.0.

Quality 4.0 represents the knowledge and philosophy of understanding the aspects and trends of Industry 4.0 and its fundamental characteristics, such as virtual system, real-time work, modularity, and the ability to be preventive, simulate, and understand the relationships that Industry 4.0 establishes. Improving any process in an organization contributes to the development of the organization's competitiveness. Therefore, it is necessary to manage quality properly in Industry 4.0. Quality is imperative in

business.

The concept of Quality 4.0 has emerged as a response to the demands of Industry 4.0, where digitalization and automation have transformed the way we work and produce goods. To define Quality 4.0, it is necessary to develop a framework that takes into account the specific characteristics of this new industrial revolution. The first step in developing such a framework is to identify the key features of Quality 4.0. These may include, among others, the use of big data and analytics, the integration of advanced technologies such as artificial intelligence and machine learning, and the implementation of continuous improvement processes that are data-driven and agile. Once the key features have been identified, the next step is to define the scope of Quality 4.0. This may involve identifying the industries or sectors that are most likely to benefit from Quality 4.0, as well as the specific quality metrics that will be used to measure the effectiveness of Quality 4.0 processes.

Another important aspect of developing a framework for Quality 4.0 is to identify the stakeholders who will be involved in the process. This may include manufacturers, suppliers, customers, regulators, and other relevant parties, and it will be important to ensure that their needs and requirements are taken into account when defining the concept of Quality 4.0.

Finally, the framework for Quality 4.0 should include a roadmap for implementation, which outlines the steps that will be taken to achieve the desired outcomes. This may involve the adoption of new technologies and processes, the training of employees, and the establishment of new partnerships and collaborations.

In summary, the development of a framework for defining the concept of Quality 4.0 requires a thorough understanding of the key features, scope,

stakeholders, and implementation roadmap. By taking these factors into account, it is possible to create a comprehensive and effective framework that can help organizations to achieve the full benefits of Quality 4.0.

However, Quality 4.0 requires more than just technological advancements. It raises the bar for stakeholder requirements by elevating them to a new level. New technology becomes one of the foundational components of the Quality 4.0 approach.

This paper focuses on the significance of Quality 4.0, highlighting the knowledge required by managers to keep pace with the rapid changes that Industry 4.0 brings.

## 2. Literature review

Quality 4.0 refers to the fourth generation of quality management, which is based on modern technologies such as artificial intelligence (AI), the Internet of Things (IoT), and cloud computing to ensure greater efficiency and precision in quality management (Carvalho et al., 2021). In this context, AI can be used to predict quality by analyzing data and predicting potential quality problems before they occur (Sader et al., 2022). Moreover, AI can be used to automate quality control by automatically identifying and correcting quality problems in real-time, optimizing processes, and primarily analyzing processes to identify areas for improvement to increase quality and efficiency (Ament & Goch, 2001). Ultimately, one of the fundamental advantages of using AI is analyzing large amounts of data related to quality to ensure a better understanding of trends and potential problems.

The most critical application of AI in quality management is automated quality control. Automated quality control leverages AI to automatically detect and correct manufacturing errors. Machine learning

algorithms are used to analyze production data to identify trends and issues (Dilthey & Heidrich, 1999). This technology can also automatically determine product acceptability criteria and evaluate the quality of each product. This enables faster and more accurate decision-making regarding product acceptability and reduces the risk of releasing low-quality products into the market (Escobar et al., 2021). By embracing automated quality control, organizations can enhance their quality management practices and deliver high-quality products to their customers.

Furthermore, since Industry 4.0 emphasizes the collection of a large amount of data, there is a challenge in analyzing them, especially when it comes to management systems. In this context, if we talk about data analysis and reporting using artificial intelligence, machine learning algorithms analyze the data to identify trends and problems, and based on that, automatically generate reports and recommendations for improvement (Sader et al., 2022). This technology enables fast and precise data analysis and facilitates decision-making regarding improvements in processes and products. The results also help reduce the risk of releasing low-quality products and increase production efficiency and effectiveness (Sader et al., 2022).

In general, the concept of Quality 4.0 emphasizes the automation and digitalization of processes through the use of technologies such as AI and IoT, increased accuracy in assessing and predicting quality, agility and fast response to quality issues, agility in adapting processes, integration of data from various sources, and ultimately increased efficiency in quality management (Nenadál et al., 2022). In this context, efficiency is increased through the automation of processes using artificial intelligence and digital technology that automate quality control processes and eliminate errors (Aziz & Dowling, 2019). Similarly, predicting

problems through machine learning algorithms enables the prediction of issues in processes and products, which allows for the preventive resolution of problems before they reach the final product (Larson & Boland, 2019).

### **2.1. Industry 4.0**

Industry 4.0 is a new trend in manufacturing that relies on advanced technologies such as artificial intelligence (AI), the Internet of Things (IoT), robotics, 3D printing, and more (Buntak et al., 2019). AI and machine learning (ML) technologies are used in Industry 4.0 to automate and improve production processes. They enable manufacturers to use data algorithms and models for automated decision-making, data analysis, fault prediction, and production process optimization. AI and ML also help to reduce production time and costs while increasing efficiency and productivity (Kovačić et al., 2022). Regarding the second most important technology of Industry 4.0, IoT, (Madakam et al., 2015) explain that this technology enables the connection and communication between various devices and sensors in the production environment.

This allows for the automatic collection of data on production processes, device activities, and product quality. IoT also enables devices and production processes to be managed remotely and dynamically adjusted to production needs (Makadam et al., 2015). Furthermore, IoT technology helps improve production efficiency and quality, as well as reduce time and costs in production as discussed in (Farooq et al., 2015).

Generally speaking, Industry 4.0 emphasizes greater automation in the production process, increased use of artificial intelligence and data analytics, increased connectivity among production machines and equipment through the Internet of Things, improved flexibility and adaptability of production, and increased

personalization of products and services (Buntak et al., 2021). All of this provides the possibility of insight into the performance that production processes develop in real-time, which also allows for the identification of opportunities for improvement. One of the particularly significant advantages highlighted, in addition to those mentioned, is increased connectivity and compatibility, which refers to the cooperation of different technologies and systems in the production process as described in (Burns et al., 2019). This includes linking different machines, devices, sensors, and networks to ensure real-time communication and data sharing. This level of increased connectivity enables manufacturers to respond more quickly and efficiently to changes in demand and the market and to adjust production according to customer needs. This also leads to a reduction in losses and an increase in efficiency in production processes.

In addition, it is worth mentioning digitalization, as discussed by Sanchez et al. (2020), refers to the use of information technologies and data networking to create a centralized database for all production processes. This integration of data enables manufacturers to quickly access information on production, products, and operations, and to use it to make decisions on improving production efficiency and quality (Sanchez et al., 2020). Increased digitalization also leads to greater security and transparency in processes, which helps prevent errors and ensures continuous improvement in production.

Increased adaptability and flexibility of production, also an important component of Industry 4.0 emphasized by Fragapane et al. (2022), refers to the ability of manufacturers to quickly and efficiently change their production to respond to changes in market demand. This is achieved through the use of highly automated and connected technologies, which enable fast and easy changes to the production process. This

production flexibility allows manufacturers to respond to market and customer needs faster and more efficiently, ensuring success in a dynamic market environment. It also leads to greater competitiveness and innovation in production. However, despite all the advantages mentioned, there are also several drawbacks (Fragapane et al., 2022). The main drawbacks include high costs of implementation and upgrading of existing equipment, the need for experts to work with advanced technologies, cyber security and the risk of hacking attacks, incompatibility and obsolescence of technologies and devices, and difficulties in adapting workers to new technologies and processes, etc. (Kovačić et al., 2022).

## 2.2. A framework for Quality 4.0

Quality is a key dimension of products and processes. It is considered a competitive advantage for companies and organizations in the global market. Quality models and practices have gone through several evolutionary steps throughout modern history - from inspection, control, and quality assurance, to quality management and design quality. These quality models follow the evolution and revolutions in the industry (Zonnenshain&Kenett, 2020).

Industry 3.0 is accompanied by Quality 3.0, which has been particularly intensively developed in the last decade of the twentieth century and the first two decades of the twenty-first century, through international standards such as ISO series 9000, 14000, 27000, 31000 and others. The Quality Management System (QMS) standard series ISO 9000, along with the ISO 27000 series (Information Security), have followed the technology of the third industrial revolution (Perović, 2019).

The concept of "Industry 4.0" was presented at the Hanover Fair in 2011 to describe the fourth industrial revolution. It is based on

digital transformation to find adequate responses to disruptive changes related to customers, organizations, and organizational boundaries. New business models have been developed for it, emphasizing trust, transparency, and security through digitization. The first introduction of the term "Quality 4.0" was in the American Society for Quality (ASQ) Future of Quality Report in 2015. Based on this approach, we can expect a renaissance of quality tools and methods through themes (Arsovski, 2019):

- Quality as inspection.
- Quality as design.
- Quality as empowerment, i.e. TQM (Total Quality Management) and Six Sigma for a holistic approach to quality, greater responsibility, and empowerment of everyone for continuous improvement.
- Quality as discovery, in adaptive and intelligent environments for solving challenges and problems.

To follow Industry 4.0 requires more knowledge than previously needed. This demands a more advanced approach to quality to understand the technology and its application. What is this increased knowledge and advanced approach, and what needs to be understood? The answers to these questions can be found by resolving the causes of the inefficient automation and digitalization processes in previous applications, from the perspective of quality management principles and approaches.

In addition to the new possibilities of Industry 4.0 such as smart factories, autonomous systems, the Internet of Things, and machine learning, Quality 4.0 aims to leverage new technologies to mobilize quality management practices and organizational excellence. The focus of Quality 4.0 is to reduce costs, improve quality, facilitate compliance, and increase the efficiency of quality operations. (What is Quality 4.0).

In summary, the concept of Quality 4.0 is formulated as follows (Tadić, 2022):

*Main pillars of Industry 4.0 + Quality Control = Quality Control 4.0.*

To achieve effective Quality 4.0, it is crucial to overcome outdated beliefs and negative traditions, including traditional methods, procedures, and structures, as well as blind obedience to authorities. Quality 4.0 emphasizes the role of digital technology in transforming management systems and promoting organizational culture, as well as enhancing competencies, democratic leadership, process synchronization, teamwork, and continuous learning.

Quality 4.0 supports the digitalization of quality management, based on the digitization of quality technology, processes, and people. Its model consists of 11 axes (Arsovski, 2019): (1) data, (2) analytics, (3) connectivity, (4) collaboration, (5) application development, (6) scalability, (7) management system, (8) compliance, (9) culture, (10) leadership and (11) competence.

**Data** is crucial for continuous improvement. Without collecting and analyzing robust data, it is impossible to form future recommendations and plans for improving quality. With the help of connected Industry 4.0 devices, accurate real-time data can be used to empower agile decision-making (What is Quality 4.0). For example (Zonnenshain&Kenett, 2020):

- Collect as many different types of data and perspectives on each situation as possible.
- Use data to develop a deeper understanding of the business context and problems at hand.
- Develop an understanding of variation, both in the data and in the overall business.
- Confront uncertainty and the possibility of making mistakes.

- Recognize the importance of high-quality data and invest in reliable sources and improvements.

Quality 4.0 emphasizes the use of big data **analytics** as one of its main aspects. Data from IoT and other sources are uploaded to cloud storage and analyzed using AI-based algorithms to recommend or make decisions. Quality data mainly relates to rejections and the number, types, and causes of defects. Conclusions are drawn from quality reports based on data analysis that includes recommendations.

**Connectivity** in the proposed Quality 4.0 framework refers to the existence of quality circles within an organization, consisting of representatives from different departments. These representatives can be connected through ERP systems, where data related to quality is inputted by the quality and other departments, and reports are generated using quality tools. Quality circle meetings are held frequently, either physically or remotely, to monitor and control the quality of products and services. Real-time quality reports are presented via ERP systems using quality tools such as histograms, Pareto charts, control charts, and FMEA. The connectivity dimension of the Quality 4.0 framework ensures that all departments in the organization are working towards the same strategic direction decided by the leadership (Zulqarnain, et al., 2022).

**Scalability** in Quality 4.0 refers to the ability of the quality management system to adapt and grow with the needs of the organization. This includes the ability to add new products or services, as well as the ability to expand operations to new markets or regions. Scalability is important because it allows organizations to stay competitive in a rapidly changing business environment.

The Quality Management System (QMS) is the foundation of Quality 4.0. The QMS provides a framework for managing quality that is based on data, analysis, and

continuous improvement. The QMS is integrated with other systems in the organization, such as Enterprise Resource Planning (ERP) and Customer Relationship Management (CRM), to ensure that quality is considered at every stage of the product or service lifecycle.

**Compliance** is another important dimension of Quality 4.0. Compliance refers to the organization's ability to adhere to regulatory requirements, industry standards, and customer specifications. Compliance is critical for organizations that operate in highly regulated industries such as healthcare and aerospace. Culture, leadership, and competence are also important dimensions of Quality 4.0. These dimensions refer to the attitudes, behaviours, and skills of the people within the organization. A culture of quality and a commitment to continuous improvement is essential for the success of Quality 4.0. Effective leadership is also critical for creating a culture of quality and driving continuous improvement. Finally, the competence of the people within the organization is important for ensuring that quality goals are met and that the organization can adapt to changing circumstances.

In summary, Quality 4.0 is a comprehensive framework for managing quality in the digital age. It is based on data, analysis, and continuous improvement, and it encompasses dimensions such as data, analytics, connectivity, collaboration, application development, scalability, compliance, culture, leadership, and competence. By embracing Quality 4.0, organizations can stay competitive in a rapidly changing business environment, meet regulatory requirements and customer expectations, and drive continuous improvement across all aspects of their operations.

Adaptability means that an increased capacity to support data, users, devices, and

analytics can increase a company's scalability. This means that companies can integrate all their data sources and systems in one place, on a larger scale than was previously possible.

The **quality management system** is a conventional part of the Quality 4.0 framework and covers the existence and application of standardization, in the form of SOPs, quality reviews, improvements, management engagement, corrective and preventive actions, etc. This management system within Quality 4.0 relies on technologies that allow management to observe statistics in real-time, control panels, and the organization's KPIs. Communication of organizational policies, SOPs, and KPIs can be facilitated by using ERP-based systems within Quality 4.0. Especially in life sciences, compliance can be a major priority in quality management. Quality 4.0 can automate and digitize compliance processes and further reduce overall quality costs.

The most significant elements of Quality 4.0 are the speed of design, production, and delivery, as well as the quality of software and data processing. Some authors have developed a quality strategy that can meet the demands of Industry 4.0. The strategy is called "Open Quality" and involves freedom in creating the characteristics of a product. The concept of Quality 4.0 must inevitably follow the trends of Industry 4.0 and the technological possibilities that have emerged with it (Tadić, 2022).

The **culture** within the proposed framework of Quality 4.0 refers to the quality culture of the organization. This dimension of the Quality 4.0 framework can be assessed through the existence of quality circles and the use of quality management tools, as well as knowledge and understanding that action should be based on the conclusions drawn from the results of these tools. It involves trust in employees in organizational processes and procedures and trust of the organization in its employees. The culture

includes offering rewards and recognition for performance improvement (Tadić, 2022). Effective leadership in Quality 4.0 requires a deep understanding of key technologies driving digital transformation, including artificial intelligence, machine learning, the Internet of Things, and big data analytics. Leaders must also understand how these technologies can be used to optimize quality processes and improve the quality of products and services.

**Leadership** in Quality 4.0 requires a combination of technical knowledge, change management skills, and a commitment to continuous improvement and innovation. Effective leaders in this field must be able to leverage new technologies and data to foster excellence in quality and cultivate a culture of accountability and ownership among employees. In addition, Quality 4.0 requires a shift in leadership style from a hierarchical approach to a more collaborative and participatory approach. Leaders must be able to facilitate communication and collaboration among different teams and departments, as well as between the organization and its suppliers and customers. This requires the development of strong interpersonal and communication skills, as well as the ability to build and maintain relationships based on trust and mutual respect. Overall, effective leadership in Quality 4.0 is crucial for organizations to stay competitive and adapt to the rapidly changing business environment. It requires a combination of technical expertise, change management skills, and strong interpersonal and communication skills, as well as a commitment to continuous learning and improvement.

These competencies include an understanding of the principles of Industry 4.0 and Quality 4.0, as well as the ability to apply new technologies and tools to improve quality and operational efficiency. They also relate to understanding and applying data management and analytics approaches to

make fact-based decisions. Competent individuals in Quality 4.0 can identify opportunities for innovation and implement new business strategies and models supported by digital transformation. **Competencies** in Quality 4.0 are crucial for the success of organizations struggling with rapidly changing markets and customer needs. (Tadić, 2022).

Based on all the characteristics of Quality 4.0 mentioned above, the following benefits of its implementation can be highlighted: it improves the quality of decision-making, human intelligence, and transparency, adapts to new changes, eliminates defects, and so on.

### 3. Knowledge management in Quality 4.0

Knowledge management (KM) refers to the process or set of processes through which an organization uses individual and collective intelligence within itself to achieve its strategic goals (Calvo-Mora et al., 2015). Ultimately, it aims not only to create and/or acquire knowledge but also to include the practices involved in storing, retaining, transferring, and using available knowledge (Dovleac, 2021).

Regarding the possibility of implementing KM and tools in companies that have implemented total quality management (TQM) practices, different studies emphasize the complementarity of these two disciplines (Paulzen, 2002; Liderman et al., 2004; Molina et al., 2007). In the context of Quality 4.0, which is becoming a trend for companies that want to leverage the advantages brought by technology and Industry 4.0, the role of KM becomes clearer, and the question of data collection and effective management becomes more urgent.

Knowledge management in Industry 4.0 plays a crucial role in enabling organizations to leverage their collective knowledge and expertise to create a competitive advantage. The first aspect of knowledge management in Industry 4.0 is the use of data analytics and artificial intelligence (AI) to collect and analyze large amounts of data generated by sensors and other digital devices in the production process. This data can be used to identify patterns, optimize processes, and inform decision-making. The second aspect of knowledge management in Industry 4.0 is the use of collaborative technologies to facilitate knowledge sharing and collaboration between teams and departments. Cloud-based platforms, social media, and other digital tools can be used to create virtual communities where employees can share knowledge, ask questions, and collaborate on projects in real time. Ultimately, knowledge management in Industry 4.0 involves the use of advanced training and development programs to ensure that employees have the skills and knowledge necessary to use digital technologies in their work. This may include providing training on data analytics, AI, and other technologies, as well as broader concepts of Lean production, continuous improvement, and agile methodologies.

Overall, knowledge management is crucial for success in Quality 4.0. By utilizing advanced technologies for gathering, analyzing, and sharing knowledge, organizations can improve their quality management processes and deliver better products and services. Investing in knowledge management can be key for organizations that want to remain competitive in the dynamic business environment of Industry 4.0.

#### 4. Conclusion

The concept of quality has followed industrial and social development. Four

stages of the industrial revolution are distinguished for the first aspect of development. Current definitions or those from twenty years ago can be used for Quality 4.0, provided that they are properly interpreted, which requires understanding. Such definitions include: quality is an attitude; quality is a process of change that enables the organization to learn about the unspoken desires and needs of the customer; quality is a framework for improvement, a way of life, culture, and thinking, i.e. understanding.

Quality 4.0 aims to democratize Industry 4.0 technology, i.e. to distribute it more fairly among employees, so that it is no longer only available to privileged and rarely qualified individuals but to a larger number of those involved in continuous learning processes. Technology affects people's lives, relationships, and ability to work together. It connects individuals, machines, data, analytics, devices, and processes. The collaboration enabled by these connections is the foundation for improvements and innovations, as well as more efficient Quality 4.0.

Management knowledge plays a crucial role in Industry 4.0 as well as Quality 4.0 due to the complexity of processes, the need for fast decision-making, the development of new business models, and the need for new skills development. Organizational growth and development rely on organizational knowledge that needs to be adapted to new conditions and technologies. Moreover, it should be noted that employees' knowledge changes due to rapid technological changes that require new skills. Organizations are encouraged to create a knowledge base and to disseminate knowledge according to the needs at various organizational levels. This is imperative to enable a basic competitive advantage and to improve business performance. In Quality 4.0, management knowledge is important for managing quality processes and quality assurance in complex

manufacturing environments. Effective quality management in Industry 4.0 requires not only an understanding of quality standards but also data management skills, analytical abilities, decision-making skills, and the ability to successfully manage teams and processes.

Furthermore, the development of new quality standards and frameworks that are specifically designed for Industry 4.0 and Quality 4.0 will continue to evolve. This includes the development of new metrics and

performance indicators that can better capture the performance of digital processes and products.

Finally, the focus on human factors and the development of new skills and competencies for quality professionals will be an important aspect of future development in Quality 4.0. As technology continues to advance, the need for skilled workers who can effectively manage and utilize these technologies will become increasingly important.

## THE AVAILABILITY OF THE DOCUMENTATION REQUIREMENT TO OBTAIN THE ISO 9001:2015 CERTIFICATE IN PREFABRICATED BUILDING FACTORY- IRAQ: A CASE STUDY

**Abstract:** *The study aims to shed light, define, and diagnose the item (documentation requirement) within one of the components of the general requirements of the international standard (ISO 9001:2015) in the prefabricated building factory in Kirkuk Governorate, Iraq. The purpose of the study was to identify the reality of the availability and application of these requirements necessary to obtain the certificate of international standards, by indicating the levels of achievement of the documentation items, as well as trying to open horizons for the application of other items necessary for the factory to obtain the mentioned certificate. In order to achieve this goal, it relied on the checklists that contributed to obtaining the necessary data to achieve the goal of the study. Based on the conclusions and recommendations of the study in its theoretical and field terms, proposals were made that are consistent with these conclusions, the most important of which was the statistical results showing gaps between the actual reality of the resource management requirements to obtain the international standards certificate (ISO 9001, 2015) and the theoretical academic reality and the prefabricated building factory to address them, where a gap of 70% is considered significant in the degree of application and documentation of certification requirements (ISO 9001, 2015). To improve the performance of the prefabricated building factory in order to obtain the Certificate for International Standards (ISO 9001, 2015). The most important recommendation from the study was the need to set up a computerized database to collect information on the operations and activities of the factory so that it could be used in future analysis and documentation. The need to use both traditional and new TQM tools and train the workforce to use them, as well as the necessity to universally use the documentation clause throughout the factory.*

**Keywords:** *Documentation requirement, ISO 9001:2015 certificate, quality, prefabricated building factories*

### 1. Introduction

The issue of obtaining an international certificate of international standards (ISO

9001: 2015) has attracted the attention of researchers, as it is one of the quality standards adopted by modern administrations (Zimon et al., 2020). The organization's performance level is improved

---

Corresponding author: Mueyyed Akram Omar Arslan  
Email:

by encouraging innovative efforts while taking into account the continuous development and improvement of activities and operations (Yanto & Mahulae, 2021).

Based on this, many business organizations have begun to apply them in a manner that suits their situation and is consistent with their future aspirations aimed at developing and improving their products, helping them to obtain a competitive advantage that gives them uniqueness and distinction and makes them superior to their counterparts from competing organizations in the market (Shafiq et al., 2019). Therefore, we found it appropriate to study the documentation requirement as one of the requirements for obtaining the International Standards Certificate (ISO 9001: 2015) and the role of this requirement in the continuous improvement of the activities and operations of the organization. Based on the foregoing, and to achieve its goals, the study was divided into four sections (Sadikoglu & Olcay, 2014). The first discussed the methodology of the study; the second presented the theoretical framework; the third presented the analytical framework of the study, and the fourth concluded with conclusions and suggestions (Sá et al., 2019).

### **1.1. The study problem**

Obtaining the International Standards Certificate (ISO 9001: 2015) requires a statement of the extent of its commitment to the documentation requirement. As a result, we can present the study's problem by asking two questions:

1. What is the interest of the research factory in applying the documentation required to obtain the international standards certificate (ISO 9001: 2015)?
2. Are the reasons for not qualifying the study sample to obtain the International Standards Certificate (ISO 9001: 2015) due to the lack of

documentation requirements? Or is it for another reason?

### **1.2. The importance of the study**

The importance of the study stems from the importance of the International Standards Certificate (ISO 9001: 2015) and its positive effects on business organizations. The study tried to shed light on the efforts made by the research factory to implement the requirements of the international standard that are consistent with the nature of its activity; it is also an attempt to identify the reality of the availability and application of documentation as one of the requirements for obtaining the international standards certificate by indicating the levels of its achievement, as well as to try to open horizons to implement the other items necessary for the factory to obtain the mentioned certificate.

### **1.3. The objectives of the study**

The objectives of the study can be stated as follows:

1. Knowing the basic concepts of the international standard certificate ISO 9001: 2015
2. Evaluating the level of application and documentation of the documentation requirement from the requirements of the standard specification (ISO 9001: 2015) in order to diagnose the gap compared to the existing quality system in the study sample.
3. Determine the reasons for non-conformity and try to suggest the best ways to overcome them.
4. Develop appropriate solutions to address quality problems in the factory.
5. Providing the company with a set of proposals and recommendations to obtain the prefabricated building

factory for the international standards certificate (ISO 9001, 2015).

### 1.4. The hypothesis of the study

The study is based on the hypothesis that "the prefabricated building factory in Kirkuk governorate did not obtain the International Standard Certificate (ISO 9001: 2015) due in part to the lack of documentation requirements."

### 1.5. The study population and its sample

The study dealt with the presentation and analysis of the prefabricated building factory in Kirkuk governorate, Iraq, which is one of the factories affiliated with the Iraqi ministry of construction and housing in Kirkuk governorate.

This factory was chosen for its excellence in the integration of the manufacturing process, which helped in evaluating the production process in its various stages as well as the problems that this factory suffers from, including damage to the final or semi-finished products.

### 1.6. Methods of data collection

To obtain the data and information necessary to test and prove the hypothesis, the theoretical side has been covered in many sources that were represented by scientific references such as books, magazines, studies, and theses related to the study of factory records, as well as using the checklist called the gap analysis examination, which aims to diagnose the gap between the reality of the quality management system in an organization and the standard requirements in the international specification (ISO 9001:2015). For this purpose, the heptagonal scale was used as a specific weight was assigned to each of the paragraphs of that scale, and accordingly, the analysis was done

and the results were reached.

## 2. The theoretical framework

### 2.1. Concept and importance for (ISO 9001:2015)

The (ISO) quality management system is a standard that expresses an effective quality management system and allows organizations that meet the requirements of this standard to use the certificate (Purwanto et al., 2020). The products offered by these organizations are manufactured according to internationally accepted standards, and they are safe for use by customers (Prada Ospina & Ocampo, 2018). It is defined as "a series of instructions for organizations to establish their quality system by focusing on procedures, control, and documentation, which are supposed to help organizations identify errors and ensure the flow of operational processes to ensure a consistent level of quality (Pacana & Ulewicz, 2020)." (ISO Organization) considers it "a family name for quality management standards and organizations use it to ensure the conformity and quality of their products" (Noryani et al., 2020). It was also defined as "a set of guidelines for organizations to establish quality systems by focusing on procedures, control, and documentation. It also helps organizations to identify errors, streamline operational processes, and ensure the level of quality (Ngambi & Nkemkifu, 2015). The ISO 9000 series includes a harmonized set of general quality assurance measures applicable to any company, whether large, medium, or small, and can be used with any existing system. It helps the company to reduce internal costs, increase quality, effectiveness, and productivity and is a step towards total quality and continuous improvement. The ISO 9000 series is not a set of product specifications and does not cover industry-specific standards, as each document classifies a quality model for use

in different applications. The ISO 9000 standards were published in four parts: ISO 9001, 9002, 9003, and 9004, as (ISO 9001: 2000) represents the international standard, while (ISO 9001, 2008) represents the requirements of a quality management system through which the organization must demonstrate its ability To provide products that address customer requirements and enhance their satisfaction as well as legal controls (ISO 9004: 2008) is concerned with providing guidelines for improving the quality management system, and the recent version (ISO 9000:2008) promotes the process approach to developing quality management systems, as it is built on the belief that the desired results are achieved more efficiently when the activities and resources associated with them are seen as a process. (ISO 9001:2015) and its recent updates, we see it applied to all types of organizations, regardless of their size or work, and can help any organization that wants to achieve and implement quality standards recognized in all of its activities, operations, and dealings with its customers and clients, as organizations can achieve the following through accreditation of (ISO9001:2015)(Mihaela Ionascu, Ion Ionascu, 2017):

1. Contributes to the efficient and effective management of quality systems. (Martin, 2017).
2. Increasing the efficiency and profits of organizations by increasing confidence in their production system (Leong et al., 2012).
3. Achieving customer satisfaction by linking the process closely to its requirements.
4. Increasing and maintaining market share.
5. Increasing the effectiveness of communications among the members of the organization and raising the morale of the employees (Kutnjak et al., 2019).

6. Reducing costs, as well as reducing spoilage, obsolete inventory, and returned work.
7. Increasing the competitiveness of the organization (Hernawan et al., 2019).
8. Better control and greater preservation of the organization's systems(Hailu et al., 2018).
9. Facilitate the compatibility and harmony of the quality system with the rest of the systems (Gallego & Gutiérrez, 2017).

## 2.2. Documentation requirements, concept, and importance

The application of ISO 9001: 2015 is based on several basic principles approved by the (International Organization for Standardization). One of these requirements is authentication, which is part of the general requirements for obtaining the International Standard Certificate (Gal et al., 2020).

The word "documentation" was derived from the word "document," and the use of the term "documentation" prevailed until it became one of the common terms among those concerned in all fields of knowledge, including quality. It is stored, analyzed, and transmitted to the beneficiaries. Documentation is defined as "the provision, selection, classification, storage, dissemination, and exploitation of information"(Fonseca, 2015). The interest in this requirement came as a result of its role in organizing and facilitating activities and operations in any organization, and its relationship to the scientific approach, which has become one of the most important principles of total quality management, as well as being a measure of the organization in obtaining the certificate of international standards (Fahmi et al., 2021), as the system assumes the (ISO) documenting quality processes in all their details, parts, and stages to ensure the application of quality as an

approach, strategy, and work method.

The importance of documentation, and its positive effects on all parties related to the organization, can be stated according to the following (Dąbrowska-Świder Msc, n.d.) (Brooks et al., 2021):

**The importance of documentation for workers** (Bravi et al., 2019) (Armawati et al., 2018) (Anoye, 2015):

- A. Introducing them to the quality system and their responsibilities and authority.
- B. A means of training them on how to implement the documented system.
- C. Providing information that enables them to do their work in an appropriate manner

**The importance of documentation for the organization:**

- A. Ensure the continuity of achieving quality requirements.
- B. Demonstrate the organization's commitment to quality.
- C. reduce the possibility of errors.
- D. Reference for internal quality audit work.

**The importance of documentation for external parties:**

- A. Enhancing the customer's confidence in the organization's ability to meet their requirements and meet the
- B. Confirmation to external parties that the organization has a quality system that has been planned and documented.

### 2.3. Documentation in the ISO 9000 series

The way to improve the performance of organizations is through good management, which comes from following modern administrative work methods, which is called the quality management system, which organizations of all kinds follow. effectively and efficiently and with the

highest possible degree of accuracy without documentation, restriction, and commitment to what has been agreed upon, and considering an approach and method of work. This is the goal of good documentation of the quality management system, which is to provide workers with stability and satisfaction in the ways of completing work, carrying out tasks, using resources, and operating production lines. In this context, the ISO 9000 series of specifications work to determine how any quality system includes all the activities related to quality that can be implemented in any organization to ensure conformance to the performance specifications that have been identified and fully meet the needs of the customer (Almeida et al., 2018) (Ali, 2014) (Alhasani, 2020).

The documentation standards contained in the series of specifications (ISO 9000) represent an important part of any organization intending to implement a quality management system, and it is indeed the typical method of documentation that is most accepted in all organizations. The international specification (ISO 9000:2000) indicates that documentation "achieves the delivery of the goal, the continuity of the action, and its use, and documentation contributes to achieving the following for organizations:

1. Matching products to customer requirements and improving quality.
2. Providing appropriate training to the organization's employees.
3. Work repetition and sequencing.
4. Providing objective proof.
5. Evaluate the effectiveness and continuity of the appropriateness of the organization's quality management system.

### 3. The analytical framework of the study

This topic deals with the presentation of the data shown by the checklists used to determine the availability of the documentation requirements in the prefabricated building factory. In their formulation of questions, the researchers relied on the scale (Ali, 2014), as well as the lists issued by the Central Organization for Standardization and Quality Control, because these lists are more appropriate to the reality of the construction industry environment and show the extent of the gap between the current quality system and ISO requirements. (ISO 9001:2015), will be based on the quantitative expression of the answers in the checklists, which will be analyzed using the following statistical tools:

**A.** Use the weighted mean to find out the application rate of the requirements of ISO 9001:2015, where the number of times the answer is repeated is considered mainly in calculating the result according to the following formula:

Whereas:

X = average or mean

Xi = weights

Fi = frequencies

After comparing it with the paragraphs of the scale, it is possible to determine the level of that requirement and know the number of stages required to reach full conformity and complete documentation with the requirements of ISO 9001:2015.

After comparing it with the paragraphs of the scale, it is possible to determine the level of that requirement and know the number of stages required to reach full conformity and complete documentation with the requirements of ISO 9001:2015.

**B.** The formula for the percentage of conformity was also used, which expresses the percentage of conformity with each of the requirements of ISO 9001:2015, and the number six (6) represents the highest degree on the scale, which represents the state of complete conformity and complete documentation of the requirements of ISO 9001:2015. As previously stated, the analysis will begin with the fourth paragraph because the first three paragraphs (1, 2, and 3) are non-main paragraphs.

To calculate the size of the gap by subtracting the percentage of the number (1) The size of the gap for each checklist = 1- The percentage of conformity to come up with results that prove the hypothesis of the study.

**Table1** : Measurement items and their weights

No.	Paragraph	wight
1	completely implemented and completely documented	6
2	completely Applied and Partially documented	5
3	Completely implemented and undocumented	4
4	Partially applied, completely documented	3
5	Partially Applied and Partially documented	2
6	Partially Applied Undocumented	1
7	Not applicable Not documented	0

**Table 2:** Checklist for Documentation Requirement According to ISO 9001:2015

Documentation requirements	Conformance with ISO 9001:2015						
	1	2	3	4	5	6	7
1. The company has prepared a quality guide to the requirements of this standard, using the guidance in ISO 10013 – ISO.					*		
2. There is a manual for all procedural methods to meet the requirements of this standard.					*		
3. Name the persons responsible for approving and maintaining documentation of quality-related activities.				*			
4. The powers and responsibilities related to the preparation, distribution, review, and control of documents related to quality are defined.				*			
5. Quality-certified documents are identified and coded within the company.							*
6. Issuing, distributing, amending, and canceling documents related to the quality management system.							*
7. All forms and forms related to the quality management system are listed and standardized.						*	
8. The records required to document the results of the quality management system applications are identified.					*		
9. Periods are set for each type of record to be kept.		*					
10. There is an approved context for destroying obsolete records.							*
11. The company owns journals to document the results of the application of various activities related to quality, including corrective measures taken when cases of non-conformance appear.					*		
12. Appropriate conditions for storing records are determined to ensure that they are not damaged and are easy to refer to when needed.				*			
13. Persons responsible for approving and keeping records related to quality are identified.							*
Weighted mean (average)	6	5	4	3	2	1	0
repetitions	0	0	1	3	4	3	2
The result	0	0	4	9	8	3	2
Weighted mean (average)				1.85			
Match extent percentage				% 30			
Gap size				% 70			

Table 2 shows the checklist for the application and documentation of the quality system in the factory and the items of the documentation required according to ISO 9001:2015. This item obtained an average of 1, which indicates that the prefabricated building factory partially applies the provisions of this item and does not document it, with an application rate of 30% of the total items to be applied, which indicates the existence of a gap of (70%) The reasons for the gap are:

1. The prefabricated building factory did not follow the guidelines outlined in the ISO9001:2015 specification, and they lacked a guide for procedural methods following ISO 9001:2015 requirements.
2. There is no clear definition of tasks regarding the documentation system.

## **4. Conclusions and suggestions**

### **4.1. The conclusions**

The researchers reached a set of conclusions, the most important of which are:

1. Business organizations strive to obtain the International Standards Certificate (ISO 9001: 2015) by establishing the fundamental requirements for achieving excellence through quality.
2. To obtain the International Standards Certificate (ISO 9001: 2015), all requirements must be met with the same strength and sobriety, as no requirement can be overlooked or ignored.
3. The checklist is a good tool that enables business organizations to check and measure the availability of the requirements necessary to obtain the international standards certificate (ISO 9001: 2015), including the documentation item, and thus be able to make appropriate decisions to improve the reality of organizations in general, including the research sample, to the acceptable level for obtaining it.
4. The statistical results show that there is a gap between the actual reality of the factory in question and the theoretical academic reality of the documentation requirement specified for obtaining the international standards certificate (ISO 9001: 2015). The amount of gap when examining and comparing was (70%), which can be described as large, and clearly shows the lack of sufficient documentation requirements in the research sample to obtain, apply, and document the requirements of the certificate (ISO 9001: 2015) in the prefabricated building factory in Kirkuk, Iraq.

### **4.2. The suggestions**

1. Establishing a computerized database in order to collect data related to the organization's operations and activities in order to benefit from it in future analysis and documentation.
2. The necessity of naming the persons responsible for approving and maintaining the documents related to quality and specifying the powers and responsibilities related to the preparation, distribution, and review of the documents of quality.
3. Senior management should follow up with the Documentation Committee by coding approved documents for quality and issuing, distributing, amending, and canceling documents related to the company's quality management system. Inventory and standardization of all forms and forms and identify the records required to document the results of quality management applications.
4. The recommendation of the senior management is to follow up on the documentation committee by setting periods for keeping each type of record and creating an approved context for destroying obsolete records and making records of the results of applications of various quality-related activities, including corrective actions taken when non-conformities arise.
5. The need to generalize the use of the documentation clause and the mechanism of using the tools that can be applied to all parts of the factory and the support and backing of the senior management to apply these tools and train the workers to use them.

## AN EMPIRICAL INVESTIGATION ON THE PERFORMANCE OF THE COMPONENTS OF QUALITY MANAGEMENT: IN THE CASE OF ETHIOPIAN MANUFACTURING COMPANIES

**Abstract:** *The main issue that requires careful consideration if organizations want to surpass their competition is quality management. The ability to create high-quality goods that meet or exceed customer expectations is critical to the survival and profitability of any government or private manufacturing enterprise. The purpose of this article is to examine the performance of the quality management components in Ethiopian manufacturing firms. Based on the literature reviewed four crucial quality management components were identified (i.e. quality planning, quality control, quality assurance, and quality improvement). As a result, the variables were used to create the conceptual framework and survey questions. Descriptive statistical analysis was used to analyze the data. The results indicate that the performance of quality management components in selected manufacturing companies was found to be low throughout all tents, including quality planning, quality control, quality assurance, and quality improvement.*

**Keywords:** *Quality Management Components; Quality Planning; Quality Control; Quality Assurance; Quality Improvement; Performance; Ethiopian Manufacturing Firms*

### 1. Introduction

Currently, quality management is the standout factor that needs careful consideration if businesses are to outperform their competitors. In any government and private manufacturing firm, the key to its survival and success depends on the capacity to provide high-quality products and meet or exceed customer expectations. It is a common phenomenon that many manufacturing companies encounter issues in delivering satisfactory products to its customer at the minimum manufacturing

cost that will increase the profits and reputation of the company.

Meanwhile, in today's competitive business environment, manufacturing firms are under pressure to match particular client demands while still delivering high-quality items to the market. Moreover, it is reasonable by most of the partners that quality management issues are the stumbling piece for the investors in manufacturing companies. Besides, quality management issues were clear in all divisions. As a result, many companies have reacted to the issues by adopting broad aspects of quality and they

---

Corresponding author: Getahun Mekuria  
Email: [getahunmekuria3@gmail.com](mailto:getahunmekuria3@gmail.com)

are beginning to emphasize quality management in all elements and phases of their business rather than just operations. Quality management, despite its prominence, has been the subject of countless empirical studies, for example, see, Agarwal et al., (2013); Bayissa, (2016); Berhe & Gidey, (2016); Bhatia & Awasthi, (2017); Birhanu & Daniel, (2014); Brkić et al., (2011); Buhumaid, (2022); Claver et al., (2003); Gedif, (2019); Gutiérrez et al., (2012); Hoonakker et al., (2010); Jaafreh & Al-Abedallat, (2013); Kitaw & Bete, (2003); Lakhali et al., (2006); Martínez-Costa & Martínez-Lorente, (2008); Milanoi, (2016); Mohammed et al., (2019); Muyanda et al., (2019); Patyal & Koilakuntla, (2017); Phan et al., (2011); Tarí et al., (2007); Zeng et al., (2014); Wanza et al., (2017). Generally, most of the empirical studies focus mainly on discussing quality management practices, and principles, and examining their impact on organizational performance in various sectors. Even if, there are numerous empirical studies conducted on quality management. Still, there is an absence of empirical studies on ascertaining the performance of the quality management components. Consequently, this article critically examines the performance of the quality management components in Ethiopian manufacturing firms. This article is organized in chronological order as follows. Section two presents a related literature review of the concept, theory, definition, models, and findings on components of quality management. Section three describes the methodologies employed in the research. Section four presents the results of the research investigation and demonstrates how different manufacturing firms implement crucial quality management components. Section five interprets the analysis result. Section six shows a conclusion drawn from the research and forwards a method of how the company can

overcome issues related to quality management components.

## **2. Literature Review**

### **2.1. Concepts of Quality and Quality Management**

Regardless of the challenges in defining the concept of quality exactly, however, several scholars have defined the concept of quality from different perspectives (Saghier & Nathan, 2013). Meanwhile, Harvey & Green, (1993) summarize the concept of quality into two different comparative concepts such as quality means different things to different people, and the second is relative to a process or outcomes, subsequently, they reflected quality as an exception, value for money, transformative, and fitness for purpose. Also, based on their importance, the concept of quality can be categorized into five generic classes in terms of, transcendent, product, process or supply, customer, and values approach (Ghobadian et al., 1994). The concept of quality leads to meeting the gap between what customers expect and what they perceive (Shen et al., 2000). Indeed, the concept of quality is quite difficult for customers to understand, consequently, customers describe quality based on their actual perception (Dale, 2003). See, for example, the meaning of quality in Figure 1.

In brief, this means when we discuss anything using the concept of quality, it simply implies that we are referring to the extent or degree to which the stated requirement is met. The concept of quality management has evolved over the last decade, from a nascent set of concepts to a comprehensive framework for controlling all aspects of quality in any organization.

Quality management includes guiding and managing aspects such as staff training, supplier quality management, and product or service design; also, from a system-

structural perspective, quality management may be described as a simple three-stage process mode (Benson et al., 1991). See, for instance, Figure 2.

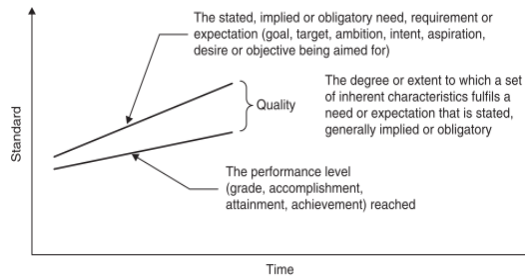

Figure 1. The meaning of quality. Source: (Hoyle, 2007)

Figure 2. System-structural view of quality management. Source: (Benson et al., 1991)

Quality management is defined as an integrated strategy for achieving and maintaining high-quality output by focusing on the maintenance and continual improvement of processes and defect avoidance at all levels and in all activities of an organization to meet or exceed customer expectations (Flynn et al., 1994). Quality management is described as a management philosophy or strategy comprised of a collection of mutually reinforcing principles, each of which is backed by a set of practices and methodologies (Sousa & Voss, p.92, 2002). Modern statistical quality control, quality improvement, and reliability operate within the concept of quality management (Bisgaard, 2007, 2008). Finally, ISO 9000 describes quality management as a coordinated action that directs and controls an organization's quality (Hoyle, 2007). Quality planning, quality control, quality

improvement, and quality assurance are examples of these activities.

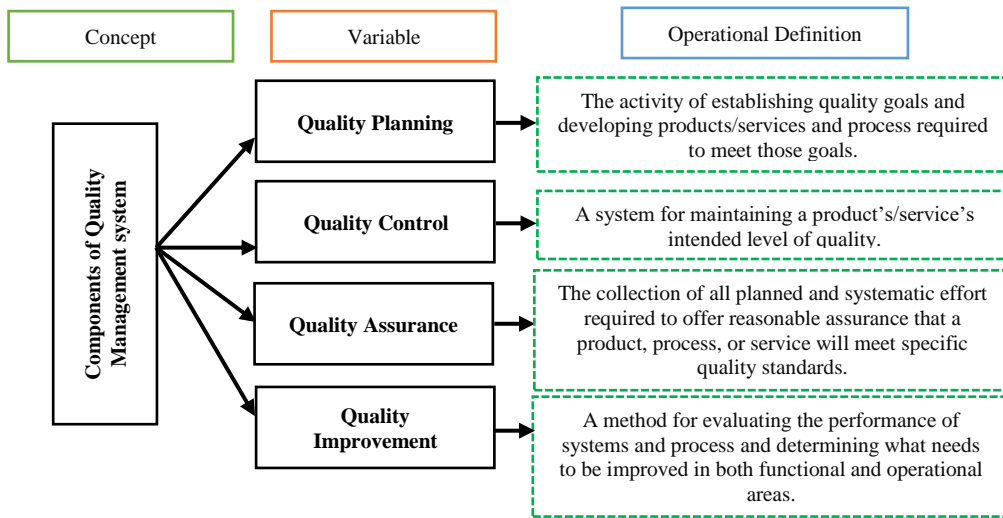

## 2.2. Components of Quality Management

To date, a great deal of studies has been done from many angles to identify the components of successful quality management, with contributions from quality leaders, formal assessment models, and empirical studies as crucial sources (Tari, 2005). It was required to identify each critical quality management component in detail for this research. Numerous scholars stated the pillars of quality management consist of quality planning, quality assurance, quality control, and quality improvement. See, for example, Table 1.

**Table 1.** Component of quality management

Components of Quality Management	Variables	References
Components of Quality Management	Quality planning	Bisgaard, (2007), (2008); Hoyle, 2007;
	Quality control	Mitra, (2016);
	Quality assurance	Tummala & Tang, (1996); Visschedijk et al., (2005);
	Quality improvement	Westgard & Westgard, (2016)

Therefore in this section, the critical quality management components are identified. Accordingly, the variables will be used to create the conceptual framework and survey questionnaires, as well as to look into the possibility of using these components in specific manufacturing companies. Conceptual Framework is shown in figure 3.

**Figure 3.** Conceptual Framework. Source: (Author survey, 2022)

### 2.3 Empirical Studies

In the previous section theories, regarding quality and quality management have been explained in detail. Further, a critical quality management component was identified. With this in mind, the conceptual framework is created using these identified variables. Therefore in this section, empirical studies will be reviewed in each quality management component in detail.

#### 2.3.1. Quality Planning

Several researchers have conducted empirical research over the last decade to explore the impacts of quality planning on different sectors. See, for example, Table 2.

#### 2.3.2. Quality Control

Similarly, numerous scholars have undertaken empirical studies to investigate the effects of quality control in various industries. See, for case, Table 3.

#### 2.3.3. Quality Assurance

This section presents empirical studies on quality assurance from various sources. See, for instance, Table 4.

#### 2.3.4. Quality Improvement

This section presents empirical quality improvement research from a variety of sources. See, for case, Table 5.

**Table 2.** Empirical studies on quality planning

Author	Research Purpose	Methods	Units of Analysis	Findings
(Lam, 1997)	Investigate the quality planning process & its perceived usefulness.	Factor & Cluster analysis	84 quality managers	Different firms could be grouped according to their strategic planning orientation & the level of planning sophistication was found to moderate significantly the strategic performance baseline.
(Senaratne & Thushangi, 2012)	Explore whether the Sri Lankan construction contractor practices quality planning effectively and the extent to which they are ready to implement strategic quality planning.	Descriptive & Inferential Statistics Analysis	3 large-scale constructing firms	ISO 9000 is the most quality management practiced by Sri Lankan construction contractors.

**Table 3.** Empirical studies on quality control

Author	Research Purpose	Methods	Units of Analysis	Findings
(Olayiwola et al., 2019)	Investigate the effect of quality control management and customer retention focusing on the dimensions of employee participation, supplier quality management, higher management commitment, and leadership enhancement in quality.	Pearson Product Moment Correlation & Multiple regression Analysis	150 respondent	+ve significant relationship between high management commitment ( $r = .659$ ), supplier quality management ( $r = .607$ ), employee involvement ( $r = .619$ ), leadership enhancement ( $r = .508$ ) and customer retention.
(Oloo, 2017)	Investigate based on two theories, Deming's theory of total quality management and the reliability theory by Rausand and Hoyland.	Descriptive Statistics & Regression Analysis	5 mobile telecommunication firms	72% of the variation in organizational performance can be accounted for by the variation in the quality control practices discussed, with the remaining 28 % being accounted for by other factors not in the model or by chance variation.
(Alzoubi, 2021)	Investigate the hotel industry in the light of process quality and quality control.	Descriptive statistics, correlation, ANOVA & regression analysis	119 hotel firms	Process quality & quality control has a significant impact on attaining competitiveness in the hotel industry.

**Table 4.** Empirical studies on quality assurance

Author	Research Purpose	Methods	Units of Analysis	Findings
(Belina, 2021)	Investigate the extent of quality assurance implementation from the inspection approach & its contribution to quality enhancement & accountability.	Thematic analysis	2 firms	The inspection strategy design at MOE did not practically implement as it was designed & it has a shortage of linkage to the operational practice.
(Sultana et al., 2020)	Empirically investigate the SQA process followed in software companies in Bangladesh.	Quantitative & Qualitative analysis	9 software companies	More than half of the companies fall short in adhering to SQA practices within their SDLC. The rest either fully or partially comply with it.
(Faller, 2018)	Analyze the impact of quality assurance on management practices & staff performance in the technical college of the Sultanah of Oman.	Descriptive-correlation analysis	233 faculty member	The relationship between all the quality assurance implementation and staff performance, implementation & management practices was significant.
(Sowunmi et al., 2016)	Investigate the software quality assurance practices of practitioners in Nigeria	Descriptive statistics	All software firms in Nigeria	It was observed that quality assurance practices are quite neglected and this can be the cause of low patronage.

**Table 5.** Empirical studies on quality improvement

Author	Research Purpose	Methods	Units of Analysis	Findings
(Maani et al., 1994)	Empirical verification of the operational & strategic value of quality improvement aims to narrow the gap between theory & practice.	Structural Equation Modeling (SEM)	184 plant	Improving quality positively enhances operational performance & productivity.
(Miller et al., 2006)	Investigate quality improvement practices of for-profit & not-for-profit hospitals.	Factor analysis	110 hospitals	Thus, underscoring the utility of quality improvement efforts despite the difference in operating characteristics, strategies & operating constraints is helpful.
(Kokemüller, 2011)	Empirically analyzing the factor influencing the success of data quality improvement.	Structural Equation Modeling (SEM)	179 respondents	Organizational implementation success is positively associated with perceived data quality, whereas no significant contribution of data quality project, to perceived data quality, could be observed.
(Mulay & Khanna, 2020)	Investigate the impact of quality (in terms of customer expectations) related to selected administrative processes in professional higher education institutions.	Partial Least Square-Structural Equation Modeling	725 respondents	The admissions process was found to have the most impact on quality, and exam & placement processes also had a significant impact on quality.

### 3. Methods

With the research objective in mind, the quantitative research method was used in this research. Descriptive statistical analysis was used to examine the performance of the quality management components in Ethiopian manufacturing firms. Meanwhile, in this research, data were collected online from the respondent using close-ended survey questionnaires. Simple random sampling was selected. 385 number of the case company's general manager, head of department/section, QMS coordinators, and quality teams are involved. The case company's employees, who were field workers (like purchasers, and sellers) and those who are newly employed and had inadequate knowledge/information for the quality management implementation were excluded.

#### Reliability Statistics

In reliability statistics, there are so many methods suggested by various literature. Among them, the most preferred method is the internal consistency method which includes (split-half, item-total correlation, and Cronbach's-alpha/coefficient alpha). Among these, the most frequently used method is Cronbach's-alpha/coefficient alpha. Even though Cronbach's-alpha/coefficient alpha is translated in numerous ways in the literature, the most common interpretation is described in Table 6.

**Table 6.** The Classification of Cronbach's Alpha Coefficient.

Cronbach's Alpha Coefficient	Interpretation of Cronbach's Alpha Coefficient
$\geq 0.9$	The internal consistency of the scale is high
$0.7 \leq \alpha < 0.9$	The scale has internal consistency
$0.6 \leq \alpha < 0.7$	The Kaiser-Meyer-Olkin (KMO) test is used in this research to determine the sampling adequacy of data that will be used for exploratory factor analysis. The KMO test
$0.5 \leq \alpha < 0.6$	The internal consistency of the scale is weak
$\alpha \leq 0.5$	The scale has no internal consistency

Source: (Sürücü & Maslakçi, 2020)

Briefly, in this research, Cronbach's-alpha/coefficient alpha was utilized to check the internal consistency of the data. The main aim of conducting reliability statistics analysis (Cronbach's-alpha/coefficient alpha) is to identify the internal consistency of the data. Therefore, Table 7 indicates that the Cronbach's-alpha/coefficient alpha value of each construct falls between  $0.7 \leq \alpha < 0.9$  which shows that the scale has internal consistency.

**Table 7.** Reliability statistics for Cronbach's alpha

No.	Construct	Item	Cronbach's-alpha ( $\alpha$ )	N

The internal consistency of the scale is high  
 The scale has internal consistency  
 The Kaiser-Meyer-Olkin (KMO) test is used in this research to determine the sampling adequacy of data that will be used for exploratory factor analysis. The KMO test also allows us to ensure that the data we have are suitable for running an exploratory

analysis and it also determines whether or not we have specified what we intend to measure. Furthermore, a KMO score between 0.8 and 1 shows that the sample is appropriate if the KMO value is less than 0.6 the sampling is insufficient for analysis. Therefore, the table below shows that the KMO test value is 0.892 which is between 0.8 and 1 indicating that the sampling is appropriate for further exploratory factor analysis.

Furthermore, the usefulness of exploratory component analysis was verified by Bartlett's test of Sphericity, which is employed as a measure of the strength of the

link between variables. The score of Bartlett's Test of Sphericity (Chi-Square) is 1,848.058, suggesting that the data were suitable to proceed with the exploratory component analysis.

**Table 8.** KMO and Bartlett's test.

KMO & Bartlett's Test

Source: (Author survey, 2022)

Note: Extraction Method: Principal Component Analysis

The primary objective of doing exploratory factor analysis is to identify the important factors or dimensions of competing priorities. To assess the number of components to keep for quality management, the researcher applied the notion of Kaiser's rule (Eigenvalue >1), but with a more interpretable factor loading. Similarly, the leftmost section of the preceding table represents the variation explained by the first solution; only four components in the initial solution have Eigenvalue >1, and the entire cumulative percentage weights 77.269 percent of the variability in the original variables. This suggests that four hidden influences are linked to quality management. However, the remaining components are unexplained variances since their Eigenvalue is less than one. Likewise, the rightmost half of the preceding table represents the variation explained by the extraction factor

after rotation.

The rotation factor model makes minor modifications to all four components. Following the completion of the aforementioned stage, which is the KMO and Bartlett's Test of Sphericity, the researcher conducted exploratory factor analysis utilizing the principal component extraction method with quartimax rotation and Kaiser Normalization. Kaiser normalization is used to provide solution stability across samples; in this analysis, all elements have equal weight while rotating. Similarly, quartimax is used for orthogonal rotation because it finds overall factors as well as optimizes squared loading such that each item loads most strongly onto a single factor. Similarly, orthogonal rotation analysis presupposes that all factors are independent or unrelated to one another.

## 4. Results and Discussion

This section presents the descriptive statistics analysis of the research investigation and demonstrates how different manufacturing firms implement crucial quality management components. Based on the descriptive statistics obtained, under quality planning, there are six sub-criteria. Among these companies, employees are given adequate time to plan for and test improvement (-0.942) and each department and workgroup within this company/division/team maintains specific goals to improve quality (-0.849) that is exceptionally skewed negatively (-0.942). Under quality control, there are six sub-

criteria. All of them are skewed negatively. However, the quality and supervision organization is sited enough to ensure satisfactory quality control in the companies (-1.938), the company/division/department/teams have adequate knowledge to challenge quality control results in the organizations (-1.673), and quality control is performed efficiently at the companies (-1.519) are significantly skewed negatively. Similarly, under quality assurance, there are five sub-criteria.

**Table 11.** Descriptive statistics.

Manufacturing industries			
Construct	Std. deviation	Skewness	Kurtosis
QP <sub>1</sub>	1.2050	-0.942	-0.050
QP <sub>2</sub>	0.8982	-0.849	0.182
QP <sub>3</sub>	1.0241	-0.275	-1.038
QP <sub>4</sub>	0.5021	0.000	-2.034
QP <sub>5</sub>	0.8754	-0.514	-0.283
QP <sub>6</sub>	0.2148	-0.756	-0.124
QC <sub>1</sub>	0.9258	-1.938	2.643
QC <sub>2</sub>	0.7515	-0.348	-1.151
QC <sub>3</sub>	0.4602	-0.884	-1.240
QC <sub>4</sub>	0.9204	-1.673	-1.953
QC <sub>5</sub>	0.4920	-0.413	-1.860
QC <sub>6</sub>	0.4017	-1.519	0.312
QA <sub>1</sub>	0.8754	-1.321	1.450
QA <sub>2</sub>	0.4602	-0.884	-1.240
QA <sub>3</sub>	0.4602	-0.884	-1.240
QA <sub>4</sub>	0.8096	-1.159	-0.454
QA <sub>5</sub>	0.4602	-0.884	-1.240
QI <sub>1</sub>	0.8341	-1.251	1.615
QI <sub>2</sub>	0.9204	-1.673	1.953
QI <sub>3</sub>	0.8341	-0.191	-1.540
QI <sub>4</sub>	0.4920	-0.413	-1.860
QI <sub>5</sub>	0.8754	-1.321	1.450
QI <sub>6</sub>	0.4920	-0.413	-1.860

Source: (Author survey, 2022)

The companies/divisions/departments/teams view quality assurance as continuing the search for ways to improve (-1.321), and the company has an independent quality assurance department within the company (-1.159) that is strongly skewed negatively. Finally, under quality improvement, there are six sub-criteria. All of them are skewed negatively. Nonetheless, the company/division/department/teams provide highly visible leadership in maintaining an environment that supports quality improvement (-1.251), and the

company/division/department/teams allocate adequate organizational resources (e.g finance, people, time, and equipment) to improve quality (-1.673), and quality improvement only involves managers (-1.321) are significantly skewed negatively.

## 5. Conclusions

The present research contributes to the dearth of research on quality management components in emerging manufacturing companies, particularly in Ethiopia, whereas past research has solely, focused on the total quality management practices, however, this article has focused on exploring the crucial quality management components that are significant for the success of any manufacturing companies. And investigate the challenges of implementing crucial quality management components. Besides, for effective usage of quality management, participation, individual association, group soul, devotion, communication, and a qualified workforce are required. And normal preparation, best administration, worker engagement, arrangement, adequate asset assignment (individuals, machines, crude materials), and rectifying documentation are all vital. The outcome of the descriptive analysis support that the practicality of quality management components in selected manufacturing companies was found to be low throughout all tents, including quality planning, quality control, quality assurance, and quality improvement, according to an analysis of the quality management components self-assessment report evaluation.

## THE INFLUENCE OF DIGITAL MARKETING ON CONSUMER BUYING INTEREST ON SHOPEE MARKETPLACE IN SOCIETY 5.0 (PEKANBARU CITY STUDENT CASE STUDY)

**Abstract:** This study aims to determine the effect of digital marketing on consumer buying interest in the Shopee marketplace in Society 5.0. This study uses a sample of 100 respondents, the respondents are Pekanbaru city students who have visited the Shopee marketplace. Sources of data used are primary data and secondary data, and the data collection method in this study used a questionnaire. The test used to test the research instrument is in the form of validity and reliability tests. The data analysis technique used descriptive statistics, classical assumption test, and simple regression analysis. The results of this study indicate that the independent variable of Digital Marketing can affect the dependent variable of Consumer Buying Interest. Based on the results of partial hypothesis testing, the independent variable Digital Marketing has a significant and positive effect on Consumer Buying Interest.

**Keywords:** Digital marketing, buying interest, Shopee, consumers, Society 5.0

### 1. Introduction

The internet is an information medium that provides convenience and facilities in obtaining the information needed. With advances in the field of information and communication technology, the world no longer recognizes the terms boundaries, distance, space or time (Margaretha, 2017; Wijaya et al., 2021; Handayani et al., 2022). In research conducted by Google and Temasek with the theme economy SEA 2018, the number of internet users in Indonesia was named the largest in Southeast Asia. In the Southeast Asian region there are 350 million internet users and 150 million from Indonesia (Hidayat et al., 2021; Putera et al., 2022; Norrahmiati et al., 2022). The more

advanced technological developments are also followed by the development of media, both online and electronic media. Now media online is not only used to find information, but online media has also become a business land or now often referred to as an online e-commerce business (Wijaya & Oktavianti, 2019; Wanidison & Shaddiq, 2021; Irpan et al., 2021).

E-commerce is an alternative for people who want to shop or find services such as online milk transport without having to meet and negotiate (Mewoh, Tampi, & Mukuan, 2019; Wagiono et al., 2022; Joko et al., 2022). Through survey data conducted by the Indonesian Internet Service Providers Association in 2020, Shopee is a popular Shopee marketplace with a percentage of

27.4% beating lazada, tokopedia, and marketplaces (Rizal et al., 2020; Surti et al., 2022). Shopee has a variety of features, namely; website, search engine marketing, email marketing, and social media marketing (Iyansyah et al., 2021; Shaddiq et al., 2021; Rizani et al., 2022).

Based on the results of survey, it shows that shopee users are millennials who average age 20-24 years. Which is generally at this age are millennials who have undergone education or as students. Generally, students do online shopping not based on needs alone, but for the sake of pleasure and lifestyle so as to cause someone to be extravagant or better known as consumptive behavior or consumerism behavior.

### **1.1 Problem formulation**

Apakah Digital Marketing has a significant effect on Consumer Buying Interest in Shopee Marketplace (Pekanbaru City Student Case Study)

### **1.2 Research objectives**

To see if there is a significant influence of Digital Marketing on Consumer Buying Interest in Shopee Marketplace (Pekanbaru City Student Case Study)

Benefits of research:

#### **a. Practical Benefits**

This research is expected to provide the right insights and strategies in the field of marketing that are able to attract the attention of consumers more than ever, and can be a material for strategic research for companies.

#### **b. Academic Benefits**

This research can be an example or guideline in making other scientific papers, and is also expected to add insight to readers.

## **2. Review the library**

### **Consumer Concerns**

Consumer behavior is the study of individuals, groups, and organizations selecting, buying, using, and utilizing goods, services, ideas, and experiences satisfying needs and their desires. According to Kertamukti (2015) a Brand Ambassador is an individual who is well-known (public figure) in a public for awards other than the products he supports. According to Setiadi(2019) to understand consumers and develop the right marketing strategy, we must understand what they think (cognition) and they feel (affection), what they do (behavior), and where (events around) that affect and are influenced by what the consumer thinks, feels, and does (Arizal et al., 2021; Fadilurrahman et al., 2021; Habibah et al., 2021).

#### **1. Factors affecting Consumer Behavior**

According to (Suharno&Sutarso, 2010) Stated that there are four main influencing factors in making a purchase, namely as follows: (1) Cultural Factors (2) Social Factors (3) Personal Factors (4) Psychological Factors.

### **Consumer Buying Interest**

According to Kotler and Keller (in Satria, 2017) consumer interest is the behavior of a person who has a desire to choose atau even buy a product, based on experience in choosing, using and consuming a product (Saputra et al., 2020; Norrahmi et al., 2021). Buying interest arises from experience and thinking so as to create motivation and become a strong desire to meet needs by actualizing those in one's mind. According to Putri (2018) consumers' buying interest is a process that exists between alternative evaluation and purchase decisions. After consumers evaluate existing alternatives, consumers have an interest in buying a product or service offered.

1. Consumer Buying Interest Indicator  
According to Tjptono (2007, in Masyithoh & Novitaningtyas, n.d.) : (1) Transactional Interests (2) Referenced Interests (3) Preferential Interests (4) Exploratory Interests.

### Digital Marketing

According to Puthussery (2020) digital marketing is the promotion of goods and services by utilizing digital technology, cellular, visual advertising, and other media. Digital marketing is based on online and offline internet systems that can build, promote, and distribute brand quality to all digital end users. According to Chaktin (2019) digital marketing or digital marketing is all efforts made in terms of marketing by utilizing internet-connected

devices with various strategies and digital media with The goal can be to communicate with consumers with online channels.

1. Indikator Digital Marketing  
According to Ryan (2009) namely: (1) Website (2) Search Engine Marketing (3) Email marketing (Social Media Marketing).

### 3. Research framework

The research framework is shown in figure 1, by hypothesis:

$H_1$ : There is a significant influence of *digital marketing* on consumers' buying interest in the shopee marketplace (Case study of Pekanbaru city students).

Figure 1. The research framework

### 4. Research methods

Method quantitative researcher. The type of population in the study ini is Non-Probability with the population being students of Riau Islamic University. The sampling technique uses Purposive Sampling Technique, with the following criteria: (1) Students who have visited the Shopee Marketplace (website/application), (2) Active students from 3 Pekanbaru campuses (3) Students who have received information from e-mail and Shopee Application. Jumlah Sampling determination uses a formula from Lemeshow (1997) and obtained result 96 which will be rounded into 100 respondents.

The sampling technique uses a questionnaire in the form of a google form (Gform).

### 5. Results and discussion

#### A. Validity Test

Based on the table 1, it can be seen that all R-count values > 0.195 which means all data valid.

#### B. Reability Test

From the results of the table 2, the Cronbach Alpha value is > 0.6, which means all data reliable.

**Table 1.** Validity Test

VARIABLE	ITEMS	PERSONS CORRELATION R CALCULATE	R TABLE	INFORMATION
DIGITAL MARKETING (X)	X01	0,891	0,195	VALID
	X02	0,932	0,195	VALID
	X03	0,942	0,195	VALID
	X04	0,956	0,195	VALID
	X05	0,963	0,195	VALID
	X06	0,950	0,195	VALID
	X07	0,958	0,195	VALID
	X08	0,947	0,195	VALID
	Y01	0,972	0,195	VALID
	Y02	0,953	0,195	VALID
	Y03	0,961	0,195	VALID
	Y04	0,967	0,195	VALID
	Y05	0,978	0,195	VALID
	Y06	0,974	0,195	VALID
	Y07	0,972	0,195	VALID
	Y08	0,979	0,195	VALID
BUYING INTEREST (Y)				

**Table 2.** Reability Test

Variable	Cronbach's Alpha	N Of Items	Information
Ambassdor Brand (X1)	0,982	8	Reliable
Trust (X2)	0,991	8	Reliable

**C. Classical Assumptions**

**1. Normality**

It can be seen from the table 3, indicating a significant value of  $0.165 > 0.05$ , which means that the data is distributed normally and is feasible to test.

are distributed normally and there are no symptoms of multicollinearity

**2. Multicollinearity**

From the table 4, it can be seen that the variable X1 has a tolerance value of  $1 > 0.10$ . Then it can be concluded that the data

**3. Heteroscedasticity**

From the figure 2, it can be seen that the dots spread out and there is no forming any pattern, which means that there are no symptoms of heteroscedasticity.

**Table 3.** One-Sample Kolmogorov-Smirnov Test

		Unstandardized Residual
N		100
Normal Parameters <sup>a</sup>	Mean	.0000000
	Std. Deviation	3.87716482
Most Extreme Differences	Absolute	.226
	Positive	.141
	Negative	-.226
Kolmogorov-Smirnov Z		2.263
Asymp. Sig. (2-tailed)		.165

**Table 4.** Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	5,371	2,113		2,542	,013		
	X	,861	,062	,816	13,952	<,001	1,000	1,000

a. Dependent Variable: Y

**Figure 2.** Scatterplot

### D. Simple Linear Regression Test

$$Y = a + b1X1$$

$$Y = 5,371 + 0,861X1$$

- Constant: 5.371

It can be interpreted that the Digital marketing variable (X) has not changed and

its value is fixed, then the Buying Interest variable (Y) value is 5,371

- Coeffesien X:0.861

If the value of the Digital Marketing variable increases by 1% then the Buying Interest variable (Y) will also increase by 0.861

**Coefficients<sup>a</sup>**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	5,371	2,113		2,542	,013
	Digital Marketing	,861	,062	,816	13,952	<,001

a. Dependent Variable: Minat beli

**Figure 3.** Coefficients

### E. KoeTestPhysioficial Determination

Based on the figure below, it can be seen that the coefficient result of determination ( $R^2$ ) is 0.751 derived from the squaring value of  $0.867 \times 0.867 = 0.751$ . The magnitude of

the coefficient of determination (*R Square*) is 0.751 or equal to 75.1%. This figure means that the *Digital Marketing* (X) variable partially affects the Consumer Buying Interest (Y) variable of 75.1%.

While the rest (100% - 75.1% = 25.9%) is influenced by other variables outside this regression equation or variables that are not studied. So it can be concluded that the free

variable, namely Digital Marketing, is able to influence the bound variable, namely Consumer Buying Interest.

**Model Summary**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	,867 <sup>a</sup>	,751	,748	2,960

a. Predictors: (Constant), Digital Marketing

**Figure 4.** Model Summary

**F. Hypothesis Test**

1. Partial Test (T Test)

T-test for Digital Marketing variable (X)  
 Based on the results of testing the hypothesis of product variation variables (X) showed a calculated t value of 13,952 > 1,984. Significant values of 0.01 < 0.05. So it can be concluded that product variations partially have a positive and significant effect on the influence of Digital marketing on consumers' buying interest in the shopee marketplace (case study of Pekanbaru city students).

**6. Discussion**

**1. The Influence of Digital Marketing on Consumers' Buying Interest on Shopee Marketplace (Pekanbaru City Mhasiswa Case Study)**

From the results of the tests that have been carried out, it is shown that Variabel Digital Marketing (X) has a positive and significant effect on Consumer Buying Interest (Y). So it can be concluded that the better digital marketing based on websites, search engine marketing, email marketing, and social media marketing, the more it will increase consumers' buying interest in the Shopee marketplace. This research is in line and strengthened by research conducted by (Masyithoh&Novitaningtyas, 2021; Kurniawan et al., 2021) which states that digital marketing variables have a positive and significant effect on buying interest.

**7. Conclusion**

1. The results showed that the Digital Marketing variable (X) had a positive and significant effect on the dependent variable, namely the consumer Buying Interest variable (Y.) So it can be concluded that the better Digital marketing is able to influence and encourage consumers' Buying Interest in the shopee marketplace (case study of Pekanbaru city students).

**7.1 Suggestion**

1. Further improve new Digital marketing strategies, and be able to provide innovations along with the development of Digital marketing. Improving the website to make it more practical and easier for consumers, as well as doing more vigorous promotions on social media, and making improvements to the shopee application which makes it easier for consumers to shop online.
2. It is hoped that this research can open wider insights both theoretically and practically. And it is hoped that this research can be carried out in depth such as adding variable ppcadvertising, affiliate marketing, online relationships, consumer relationship management and many more. By taking more and more diverse samples, such as all groups such as employees, students and housewives and others so that the results obtained are better and spread.

## MODEL OF DEVELOPMENT AND IMPLEMENTATION OF IMS

**Abstract:** *This paper analyzes how a systemic approach to management can be used to facilitate the development and implementation of an integrated management system (IMS) within an organization. It is argued that every solution for integrating management systems requires two elements: a conceptual model and a supporting methodology. While research on IMS modeling is quite extensive, the development of methodologies for achieving fully integrated systems is still not at a satisfactory level. In the IMS acronym, particular emphasis is placed on the I (path to integration). The label M (Management) refers to the desired level of quality, while S (System) represents the methods and activities necessary to achieve the desired goal. It should be noted that all three concepts are directly related. From the above, it can be concluded that the development of IMS represents a broad field of diverse approaches. The paper presents an original model for the development and implementation of IMS systems, thus providing an approach and a set of criteria for selecting the most appropriate IMS model.*

**Keywords:** *IMS, integration, system, PDCA, synergy, model, management*

### 1. Introduction

In extensive literature in this field, there are numerous models of IMS. The research analysis aims to highlight the common integration models of several IMS, aspects related to IMS implementation, the benefits of IMS implementation, and the nature of integration strategies [11]. The research results provide valuable information that can be used to encourage the application of integrated management systems. Integrating documentation, followed by aligning internal objectives, processes, and finally resources, is one possible approach. Some companies integrate parts of MS documentation (e.g., policies), while others aim for full integration of objectives, processes, and resources. Therefore, partial and complete

integration are possible. Quality, environment, and safety are the most common, as the basic standards are easily accessible. Corporate social responsibility is also essential. In what order should selected management systems be introduced? This depends on existing systems and focus. Quality, followed by the environment and safety, is the most common order. Other possible sequences are considered by Karapetrović and Villborn (1998b), BPMJ. However, the practicality of this ultimate level of integration will probably be debated for a long time. [35]

### 2. Prerequisites for IMS

Moreover, companies should present their quality product and service-related issues.

---

Corresponding author: Jovan Sofranac  
Email: [asofranacd@gmail.com](mailto:asofranacd@gmail.com)

From these needs, the concept of integrated management systems (IMS) has been developed. In theory and practice, the question is posed as to why some companies integrate their management systems, while others with similar contexts do not even accept specific management systems. Understanding decision-making regarding IMS and the motivations that influence IMS implementation is crucial for two reasons: First, it will help theorists predict behavior during IMS implementation, and second, IMS will identify the mechanism that encourages implementation.

Effective communication of strategies and policies is critical to the sustainable success of an organization. Communication should be purposeful, timely, and continuous. A process-oriented approach based on the PDCA concept should be considered vital support, regardless of the methodology applied.

What are the necessary levels of integration? For example, Jonker and Klaver (1998) mention five: political, conceptual, systemic, normative, and pragmatic. It should be possible to use a common structure of policy, goals, control routines, monitoring, and improvement for general management. This is the way to achieve business goals through planning as a process that relates to the entire business system. In order to achieve defined goals, changes must be made in the business system, primarily in culture. Culture is made up of tradition, habits, and accepted behavior that are partly inherited and partly can be influenced by it. Culture is not a static concept, it develops slowly and is reflected in the policy of the business system, which is the basis for planning [39]. There is no unanimous definition of organizational culture. According to Gallea and Ghobadian (2004), some scholars describe culture as "shared values", another group as "way of working", and a third group considers it a combination of both.

However, there is a general consensus that culture is a dynamic concept that can be learned (Schein, 1990). Cultural changes can only be a matter of adapting to company values, not a true change in behavior. The authors suggest that while culture can be managed and specific values changed, the rationale for change affects the success of change efforts. It becomes critical that all participants understand the principles to be adopted and participate in their implementation: "the success assessment of change programs depends on the perception of what changes are supposed to achieve" (Ogbonna & Harris, 1998, p. 285).

A quality culture requires a combination of organizational culture, individual culture, and quality principles (Detert et al., 2000; Hildebrandt et al., 1991; Kanji & Iui, 1997). A strong quality culture includes customer orientation, continuous improvement, using data and analysis to support decision-making, and involving people in quality issues (Bahzad & Irani, 2008; Briscoe et al., 2005; Ishikava, 1984).

Vision is a guiding force that is the result of three components: openness, spontaneity, and a sense of reality. Openness is directed outwards, while spontaneity is directed inwards, accepting various positions from which the functioning of the system is observed. The synthesis of openness and spontaneity must be based on reality if we want the vision to succeed. Management values can stem from the vision and can be a powerful tool for consistent implementation of management in practice. [39].

### 3. IMS definition

The Integrated Management System (IMS) is defined as a set of interrelated processes that share a common set of human resources, information, materials, infrastructure, and financial resources to achieve composite objectives related to satisfying various stakeholders [1,2,3,4]. The Integrated

Management System (IMS) represents a management system that integrates all components of the business into a coherent system to enable the achievement of its purpose and mission through an integrated approach [5,6,7]. Quality, environment, and occupational health and safety often form the core of the IMS. Compatibility provides the opportunity to integrate the three systems into the organization. However, it should be noted that the three systems have their own specificities. ISO 9000 is customer-focused, ISO 14000 aims to support environmental protection and pollution prevention while promoting social and economic harmony, and OHSAS 18001 emphasizes proactive professional risk control and allows the organization to improve its safety and health of employees [9]. Resources include human and financial resources. The use of resources requires consideration of the similarities and compatibilities of the three systems in implementation. [5,6,7]. Different companies have different management practices for defining their mission, vision, strategy, including budget preparation, performance control, and motivation. It can be seen that there has been no real attempt to integrate the economy into the ISO system. We propose the following definition for a fully integrated management system: one that involves managing all relevant stakeholder needs, including all suppliers, customers, and other stakeholders in the supply network. Top management must be actively involved in conveying organizational goals and plans and in motivating and rewarding employees. Support and commitment from top management are essential for process integration and for maintaining and improving organizational processes. Resistance to integration is expected due to a lack of a strategic plan at the enterprise level, undefined responsibilities, and weak training (Sommerville & Savier, 1997). Therefore, people learn and develop a quality culture, which exists through the values that the

organization defends, the way of working, and collective learning (Gallear & Ghobadian, 2004). The main proposal for overcoming internal difficulties is a necessary cultural change, training, and education of all employees at all hierarchical levels to improve their understanding of the process and thus their motivation. If organizations are aware of the difficulties in integration, they will face the integration process more prepared, and the likelihood of successfully completing the process will increase, and staff training could help in this challenge. This can make organizations more efficient and competitive. (Sommerville & Savier, 1997) (Antunes, Cunha, & Barata, 2014; Antunes & Cunha, 2013).

#### 4. Level of integration

The scope of integration is often limited, which indicates that it is important to define what is meant by an IMS. If it is viewed as a fully integrated IMS, the mission, vision, policy, goals, organization, and roles should be well understood and accepted by the organization. The management system (MS) includes four main elements: policy, management objectives, management responsibilities, and process definition, to ensure performance improvement [12,13,14,15]. The system should be interpreted as a whole composed of a set of subsystems that group processes, which also include activities. The organizational system is based on the organizational structure in which management functions are applied. The correlation of all subsystems (organizational, informational, decision-making, and methodological) is the basis for the organizational structure that encompasses current internal management practices. In order to be considered as integrated parts of the company's management system, it is necessary to establish mutual connectivity between these subsystems so that there are no boundaries

between the company's processes [11].

The level of integration describes to what extent different systems have become one, ranging from a low level with some coordination to complete merging. In Bernardo et al. (2009), a model with four levels (0-4) is presented, showing eight different studies and their degrees of integration. Karapetrovic (2002) presents three possible levels of integration. The first level concerns the integration of documentation, i.e., a common manual with specific procedures required by different areas in the IMS. The second level concerns the alignment of basic processes, goals, and resources, i.e., directing the use of basic processes "by integrating planning, design, implementation, and other activities vertically through management systems." The third level relates to the creation of an "all-in-one system," i.e., a universal system that manages all previous systems in the organization. The implementation of different management systems is possible because there are common principles (process approach, PDCA, risk management, etc.), specifications and methods for integration, common elements of standards, and methods for aligning the interests of stakeholders. Partial implementation of standards/systems can be achieved by [34]:

- Inclusion, by creating documentation for the basic standard/system (QMS according to ISO 9001), and then expanding it according to the requirements of other standards/systems, and
- Addition, by having each standard/system have its own documentation that is interconnected.

The core that connects all management systems into one system is a process. In order to implement an integrated management system, the business system must meet the requirements of all integration standards. The question arises as to how to

do this, or which implementation approach to apply. Implementation of integrated management systems is a process like any other, which is used to convert inputs into outputs. The inputs to this process are the requirements of standards such as ISO 9001:2008, ISO 14001:2015, OHSAS 45001:2018, etc., and the outputs are documented quality management systems, environmental protection and health and safety management systems, and other systems. Like any other process, this process can be modeled in various ways. Depending on how the process of establishing an IMS is modeled and implemented, the results obtained at the output also depend.

There are three basic approaches to implementing integrated management systems:

- Sequential approach to implementing integrated management systems
- Parallel approach to implementing integrated management systems
- Combined approach to implementing integrated management systems

Since the object of IMS implementation is a complex production-business system that needs to meet the requirements of ISO 9001:2015, ISO 14001:2015, and ISO 45001:2018 standards, there is a dilemma as to which of the above implementation approaches is optimal.

The sequential approach to implementing integrated management systems proceeds in such a way that one management system is established first, followed by the second and then the third system. Since ISO 9001 standard is the first to emerge in 1987 and serves as the basis for other management systems, it is logical to establish QMS first, although this is not necessarily a rule in all three approaches (EMS or OHSAS can be established first, depending on the needs of the organization).

ISO has not developed a standard that would guide all organizations in implementing the system, but it has published an ISO manual (2008) that provides some guidance on integration, but nothing concrete enough to be illustrated by all organizations worldwide. A very important aspect of IMS is the common structure of updated ISO standards, which ensures management in all organization processes. An organization that already has an integrated management system has an advantage over an organization that does not have an integrated system. [30]

The advantages of IMS consist of risk reduction and profit increase, reduced documentation, identification of new customers, strengthening of market position, facilitation of staff training, continuous improvement, and implementation of a vision for future development [40].

It has been analyzed that just as there are advantages, there are also barriers and risks for implementing IMS, which have been identified in the literature: [1] [6] [8] [17] [40] [32].

Our proposal is that organizations should identify their stakeholders and their needs. These needs must be met efficiently by prioritizing and using existing standards and guidelines to build an IMS. The system's structure is determined by the mission assigned by the organization's management [24].

## 5. Basic aspects of modeling

Enterprise modeling is a dynamic process that never ends. It is a process of continuous improvement that adapts to real needs. For these reasons, it is necessary to have a good understanding of the goals and current state of the enterprise.

Modeling can be done from multiple aspects. Here, the functional aspect, information aspect, resource aspect, and organizational

aspect are particularly interesting. Each of them is discussed in more detail in [39] [43].

By modeling, we more efficiently define appropriate business processes and analyze their structure. The object of modeling in this paper is the enterprise, with the aim of facilitating its integration, which involves connecting into a whole that is more than a simple collection of parts.

The British Standards Institution (BSI) has prepared a publicly available specification (PAS 99:2006), which is a methodological guide for integrating two or more management systems, whether they already exist as independent or an organization has certified one and wants to align its business with the requirements of other management systems. The specification insists on two elements:

- a systemic approach to defining all processes and documents of the management system,
- treating risks.

PAS specifies common requirements for management systems and aims to provide a framework for implementing two or more standardized management systems in an integrated manner. [34]

The PAS 99:2006 specification issued by the BSI provides a recommendation on how to integrate the requirements of different management systems.

PAS 99 takes into account six common requirements for management system standards and follows the PDCA (Plan, Do, Check, Act) approach present in all major management system standards. By combining the PDCA cycle and common requirements, the structure of the management system is defined.

The PDCA model provides the framework for an IMS based on existing and accepted philosophies of QMS, EMS, and OHSAS. The model interprets the common elements of IMS, which organizations should consider when implementing such a system. The

model also indicates that the integration of documentation and verification forms is only part of IMS, and that other elements and factors will influence the achievement of organizational goals.

## 6. PDCA cycle

Similarities between the PDCA cycle and updated standard requirements can facilitate the integration process by developing an effective integration strategy [19].

Starting from the PDCA structure, the integrated management system is a complex construction that identifies common standard models and aims to leverage the advantages of several separate systems by making them work together as a unified whole.

Based on the PDCA cycle, Zeng et al. (2007) [19] proposed an interesting strategy based on three levels of integration: (1) strategic synergy is a priority, (2) organizational structure synergy, and (3) documentation synergy. The PDCA cycle is also advocated by Rebello (2014) [21], Nunhes et al. (2016) [17], Majernik et al. (2017) [22], Bernardo et al. (2018) [18], and Souza and Alves (2018) [23], who have proposed models similar to those of Zeng et al. (2007) [19], with minor differences in implementation, which from our point of view, have a chance of success in implementing IMS. The PDCA model has more and more supporters worldwide, and more and more organizations are implementing IMS according to the PDCA model.

As a result of the analysis of proposals for implementing IMS, it can be concluded that the use of the PDCA cycle can lead to the lowest implementation costs.

## 7. Synergy

The word synergy comes from the Greek word *syn-ergos*, which means cooperation or joint work. It refers to a type of reaction

where two factors combine to give a greater common effect than the sum of their individual effects. Simply put, synergy refers to the phenomenon  $2 + 2 = 5$ . A greater common effect as a goal was also the idea for this model.

"More than the sum of its parts" is the vision presented by Cunha and Figueiredo (2005) for the development of IMS. Their work was an inspiration and starting point for expanding the scope of knowledge in this thesis. IMS deals with the principles, policies, processes, and procedures needed to achieve quality goals (Zhu & Scheuermann, 1999). ISO 9001 is one of the most popular programs for IMS implementation (Sampaio, Saraiva, & Rodrigues, 2011; Zhu & Scheuermann, 1999), leading organizations to create a documented system for managing their quality efforts (ISO, 2008a). The biggest challenge that organizations face in their efforts to implement IMS is for quality to become a daily practice, internalizing quality principles in the development of a quality culture (Briscoe, Favcett, & Todd, 2005; Ishikava, 1984; Kanji & Iui, 1997; Kanji, 1998).

The synergistic IMS model (in three levels), authors [33], was developed in China based on research studies of the implementation of quality, environmental, health, and safety management systems.

At level 2, there are three pillars: resources, organization, and culture.

The synergy of organizational culture is also significant for the integration of the management system. The synergy between different responsibilities in the integrated management system and continuous performance improvement is most likely to be established as a result of high ambitions related to the integration process. Therefore, the management system must be internally implemented through the organization and externally through relationships with participants. The synergy of positive

interactions between top management and subordinate management systems increases innovative ability, problem-solving speed, and learning ability. [33]

## 8. Model of development and implementation of tqm system

The development and implementation of an IMS system involves a long and continuous process that must involve all the resources available to the business system. In short, various implementation strategies can be used for IMS integration. However, the development approach should be tailored to the organization. We believe that an approach focused on the PDCA concept and synergy is a very efficient approach.

The development and implementation of the IMS system are a continuous process that involves all business resources. This process can be divided into 6 phases [39] [43]:

- Determining the IMS strategy
- Preparation of IMS activities
- Development of an IMS system plan and program
- Development of an IMS system
- Implementation of an IMS system
- Improvement of the IMS system

Each of these phases contains several processes that continue or run in parallel with each other. This interdependence

implies interaction from the perspective of synergy, which establishes a connection between all phases.

## 9. Conclusion

The main innovation of this research is the quality assurance approach based on synergy and the PDCA cycle. It has been shown that some human errors in quality assurance can be eliminated by proper use of synergy. In today's dynamic environment, it is not a question of whether management systems should be integrated, but which is the best for a particular organization. Since all organizations differ in their goals and established business culture, it is difficult to develop a single integration model that would meet the requirements of all organizations. For the success of management integration, it is crucial that the company analyzes the state of the company and ensures that all involved individuals understand the process before the actual start of the process. This is the only way for the implementation of an integrated management system to become an important factor in achieving sustainability. Finally, the need to align IMS with a comprehensive business strategy should always be a priority in order to provide significant support to organizational success.

## OVERVIEW OF RISK MANAGEMENT TOOLS AND METHODS

**Abstract:** Due to the lack of a risk management system, many organizations in the world have suffered significant financial losses. Therefore, it is necessary for every organization to establish a risk management system as a structural element of the management system as a whole. The problem of risk management exists as a global problem that requires global solutions. One of the possible solutions is to meet the requirements of international risk management standards ISO 31000: 2009 and use risk assessment techniques in accordance with ISO / IEC 31010. The risk management system is compatible with the quality management system ISO 9001: 2008 and is based on the same principles. If the risk is not recognized and the organisation does not cope or is unprepared for the crises, the organization can suffer great losses. The review of tools and risk management tools creates preconditions for better preparation of the organization for crises, for better coping and faster exit from the crisis.

**Keywords:** Crisis, Risk Management Measures, ISO 31000: 2009, ISO/IEC 31010:2019

### 1. Introduction

Risk represents uncertainty in the outcome of expected events in the future, i.e. it is a situation in which we are not sure what will happen, and reflects the probability of possible outcomes around an expected value where „the expected value is the average result of unpredictable situations that recur“. In order to avoid crises in which non-recognition and untimely response to risks could lead us, it is necessary to assess all internal and external factors that may lead to the realization of the risk. The ISO 31000: 2018 standard, as a separate standard, has an advisory effect on the management, emphasizing the importance of timely and preventive mechanisms for risk detection. The ISO / IEC 31010 - Risk Assessment Techniques (International Standardization Organization / International Electrotechnical Commission) standard serves to support the

ISO 31000 standard through a quality management system. The most used are: HAZOP method, HACCP analysis, Brainstorming method, Risk mapping, Bowtie analysis, FMEA method of the risk assessment system, Pereto diagram and Ishikawa diagram. By applying the techniques prescribed in the internationally harmonized and recognized standard ISO / IEC 31010: 2019, it is possible to assess the significance of individual risks to the process or project and to create preconditions for an adequate response before risks bring the organization into crisis, which can result in major problems or even be disastrous for the organization.

### 2. Crisis

According to Osmanagić Bedenik (2010), the philosophical dictionary (1982) states that crisis (Greek: krisis) means "break, a

---

Corresponding author: Davor Grgurević  
Email: [dgrgurevic@unin.hr](mailto:dgrgurevic@unin.hr)

transient difficult state in every natural, social and thought process" and that in ancient Greece the word „crisis“ meant „decision“. A crisis can be seen as an event or set of events that disrupts the current state of regular activities or as a potential threat in the future that needs to be detected in a timely manner with defined strategy to overcome or avoid it. The crisis is in most cases an undesirable situation for the organization, but it can also contain certain positive characteristics if the management responds in a timely manner and with an effective strategy, that turns the crisis in their favour. The negative characteristics of the crisis are certainly more numerous than the positive characteristics, so it is not surprising that most people perceive the concept of crisis in a negative context.

### 3. Risk and Introduction of Risk Management Measures

Srića (2011) states that "Risk represents uncertainty in the outcome of expected events in the future, i.e. it is a situation in which we are not sure what will happen, and reflects the probability of possible outcomes around an expected value" where "expected value is the average result of unpredictable situations which are repeated. Buntak and Kovačić (2020) state four types of risks in their risk matrix: dangerous risks (low probability, high impact); critical risks (high probability, high impact); minimal risks (low probability, low impact); routine risks (high probability, low impact). Observing the risks from the aspect of managers in a business organization, two types play the most important role, namely: "Business risks (occurring within cash flow), and Financial risks (related to the way the organization is financed, especially borrowing which can cause insolvency and bankruptcy.)"

The PDCA cycle (P-plan, D-do, C-check, A-act) serves as a support technique for the risk management because any action aimed at

risk cancellation is not final and requires continuous monitoring of the implemented risk management strategy with the aim of timely adaptation. The introduction of a risk management system in the organization reduces costs in the long term through preventive measures. In addition to the economic benefits for the organization, risk management creates a safer workplace by reducing business risks to a lower level. Organizations may introduce a specialized risk management department or authorize individuals or groups within individual departments to support the entire organization in risk analysis in its processes.

The following indicators appear as indicators of the necessity of introducing risk management measures:

- activity indicators: such as asset turnover ratio, current assets turnover ratio, receivables turnover ratio, inventory turnover ratio and supplier turnover ratio
- liquidity indicators: such as current liquidity ratio, accelerated liquidity ratio, current liquidity ratio and financial stability ratio
- indebtedness indicators: such as indebtedness ratio, own financing ratio, financing ratio and interest cost coverage
- cost-effectiveness indicators: such as cost-effectiveness of total business and cost-effectiveness of business (sales)
- profitability indicators: such as return on assets (ROA) - return on total assets, return on equity (ROE) - return on invested capital, gross profit margin and net profit margin
- investment indicators: such as return on investment (ROI) - return on investment, earnings per share (EPS) - earnings per share, dividends per share (DPS) - dividend per share, dividends payout ratio (DPR) - dividend payment

ratio, price per share (PPS) - total return on shares and dividend yield.

These indicators are used to analyse the business of the organization and may indicate certain imbalances in business that need to be managed in a timely and effective manner.

#### 4. Application of Standards in Risk Management

Risks are events that may or may not occur, but it is necessary to consider the broader context of events and to reduce the impact of risks on the outcome with the quality planning or to avoid them completely by continuous monitoring and adaptation of the strategy. In order to detect risks, it is necessary to assess all internal and external factors that can lead to the realization of the risk. Risk management needs to be handled responsibly and thoughtfully due to the possible damage that may result from the insufficient quality of management's approach in acting on them. Systematic risk management must be seen in the form of continuous monitoring and timely action with the aim of complete elimination or reduction of harmfulness within various departments of the organization.

The quality management department may take a decision on the implementation of the ISO 31000: 2019 standard for risk management in departments and on the implementation of the ISO 22301: 2019 standard intended for the management of continuity and consistency. The ISO 9001: 2015 standard is one of the key standards in the quality management system, and according to Džolan (2017) it "includes risk identification, risk analysis, risk categorization, control and risk reassessment." Vuković (2015) states that "the current draft ISO 9001: 2015, although it sets requirements for risk assessment, does not require the existence of a formal risk management system". The standard ISO

22301: 2019 defines guidelines for business continuity management in organizations. As a rule, it is associated with the security of information systems in which there are significant risks of personal data theft and misuse.

ISO 31000 defines the principles and guidelines of risk management and is not intended for certification, but serves to raise awareness of organizations about the possibility of implementing additional security aspects in business to prevent unwanted and unnecessary losses that may arise from inadequate approach to risk management. The ISO 31000: 2018 standard, as a separate standard, has an advisory effect on management, emphasizing the importance of timely and preventive mechanisms for risk detection. Management principles and risk assessment techniques defined in the ISO 31000 family are key prerequisites for the evolution of business towards a quality management system through the implementation of standards intended for environmental management (ISO 14001: 2015 - environmental management systems) and standards for safe drinking water supply (46001: 2019 - water safety management system for human use) by using the information on risks in processes that may harm biodiversity and human, plant and animal health through negligent handling of harmful substances. Increasing the safety of products intended for human consumption can be achieved by implementing the HACCP method, which creates control points in which the harmfulness and deviations of substances in products are examined, thus preventively responding to the possible realization of risks in consumption by end users.

ISO / IEC 31010 - risk assessment techniques (International Standardization Organization / International Electrotechnical Commission) standard serves as a support to ISO 31000 standards through a quality management system. The first version of the

ISO 31010 standard appeared in 2009, and in the meantime, it has been adapted and reissued in the form of ISO 31010: 2019. The techniques of the ISO / IEC 31010 standard consist of a wide range of qualitative and quantitative analyses which can provide a closer insight into the realization of the effects of risk in individual processes. For maximum utility of the techniques, it is necessary to educate people in managerial positions in departments in order to have a balanced effect on risks throughout the organization. The greatest effectiveness comes from a combination of the techniques themselves to get a broader picture and provide a greater chance of identifying, analysing, evaluating, and determining treatments with the objective of eliminating threats to the vitality of the organization. ISO / IEC 31010 techniques

offer both qualitative and quantitative methods of risk assessment, but each technique is unique and has a different form of application in the risk assessment process, and therefore it is recommended to combine techniques to achieve the most accurate assessment used by risk management to decide on further steps related to risk management. The usual practice of linking is based on risk assessment through techniques that provide the possibility of their identification, which is followed by support in the form of numerical evaluation, statistical analysis and creating a visual representation in accordance with the identified intensity of certain assessed risks. The current version consists of 31 techniques that provide qualitative and quantitative support in the identification, analysis, evaluation and treatment of risk:

**Table 1.** List of ISO / IEC 31010 risk assessment techniques

Oluja mozgova	Analiza uzroka i posljedica
Strukturirani /djelomično strukturirani intervju	Analiza uzroka i efekata
Delphi tehnika	Analiza slojevite zaštite (LOPA)
Liste provjere	Stablo odlučivanja
Analiza primarnih opasnosti (PHA)	Analiza ljudske pouzdanosti (HRA)
Analiza opasnosti i operativnosti (HAZOP)	Leptir mašna analiza ("Bowtie")
Analiza opasnosti i kritičnih točaka (HACCP)	Održavanje usredotočeno na pouzadnost
Procjena rizika u okolišu	Analiza informativnog kruga
"Što ako?" tehnika (SWIFT)	"Markov" analiza
Analiza scenarija	"Monte Carlo" simulacija
Analiza poslovnog utjecaja	Bayesova statistika i mreže
Analiza korijena rizika	FN krivulja
Analiza posljedica pogrešaka (FMEA)	Indeksiranje rizika
Stablo problema	Tablica vjerojatnosti i posljedica
Stablo događaja	Analiza troškova i koristi (CBA)
	Analiza višekriterijskog odlučivanja (MCDA)

Source: Kundih, D.: Risk management in the circumstances of the crisis situation, Final thesis, Koprivnica 2020, p 32.

The HAZOP (Hazard and operability studies) method is currently the first choice for identifying weaknesses in the design process and is used worldwide within the manufacturing industry. Outside the manufacturing industry, it is used in a modified form.” (Crawler and Tyler, 2015). According to Čičak (2017), one of the biggest disadvantages of this method is that „it is not possible to analyse more complex situations and complex systems, such as situations created by the simultaneous

occurrence of multiple independent events“.

HACCP (Hazard analysis and critical control points) analysis is based on the definition of critical control points within the risk assessment process and is most often used as a technique in the food industry. Critical points are a key factor in evaluating a particular service or product because of the knowledge of potential deviations from acceptable values, which provides guidelines for further action to align the end service or product with that defined in the organization

plan thus ensuring consistency and quality maintenance.

The brainstorming method is primarily a qualitative method of imaginative analysis of potential problems and solutions in a particular process. In the field of risk analysis, brainstorming can identify certain threats that may arise in the process. To manage them successfully, it is necessary to use other techniques that include a quantitative component of risk management due to accuracy and defined numerical values that describe in more detail their significance on conducting a particular project with much greater precision and the ability to rank risks according to the priorities they represent in a particular process.

**Risk mapping** - The process of risk mapping defines the identification of risks, quantification of their impact and probability, and the addition of a label that is later applied to visual tools such as a matrix display and scoring scale. Risk scoring is performed by multiplying the assumed probability of realization of the source of danger and its impact on the process itself, and for a given risk a label is set which is later incorporated into the matrix display and scoring scale. The scoring scale groups risks according to intensity through probability and impact analysis. The matrix presentation defines risks according to significance and probability. The specified matrix can determine whether it is a dangerous, critical, minimal or routine risk.

**Bowtie analysis** is a visual representation of the input values, potential hazards and outcomes that result in the realization of hazards. With this analysis, it is possible to see the broader context of a particular hazard and thus point to the need to create guidelines with the aim of effective preventive action aimed at eliminating the hazard. The wider possibility of applying bowtie analysis manifests through combining with techniques that complement

the hazards defined by the analysis by adding quantitative features that can more closely define the criteria by which management is directed towards preventive action on hazards. Šotić (2016) states that the "objective of risk analysis is to describe the risk, i.e. to present an informative picture of risk. ", and also explains that "to present such a picture in the dissertation is used a "bow-tie" diagram, which illustrates the building blocks of risk, i.e. risk analysis."

FMEA method of risk assessment system (Failure Mode and Effect Analysis) is a method that prevents risks and minimizes their impact through a planned approach. In practice, the name FMECA method (Failure Mode and Criticality analysis) is also used. According to Dobrović (2008) "FMEA is a method that maximizes customer satisfaction by completely eliminating or partially reducing the causes of potential problems. In order to achieve this, the FMEA needs to be implemented as soon as possible, regardless of the fact that not all data or information is fully known at a given time. " ISO / IEC 31010: 2019 recognizes four basic types of application of FMEA analysis: 1. FMEA system; 2. FMEA design; 3. FMEA processes and 4. FMEA services. Buntak et al. (2014) state that "regardless of the risks involved, the FMEA method can reliably assess the possibility of their realization through the calculation of RPR factors, whose acceptable values are predetermined" where the RPR factor is defined as the level of potential risk.

The Pareto diagram is a method that determines that 80% of all nonconformities account for 20% of the problem. The evaluation process consists of the detected frequency of non-compliance in the sample expressed as a percentage in the order from highest to lowest and by expressing the cumulative values which according to the ABC structure are classified into classes A (up to 80% of cumulative), B (80% up to 95% of cumulative) and C ( 95% -100% of

cumulative). This diagram can identify key risks on which management can base further guidance.

The Ishikawa cause-and-effect diagram is used to analyze the factors that lead to a particular problem through evaluating items from the problem cause groups. Based on the information obtained, the probable causes that lead to the problem can be identified. The diagram is named after the creator Kaor Ishikawa, for whom Pipušić and Grubinić (2014) state that he "advocated the thesis that quality improvement is a continuous process that can always be further improved." It is also called a fish bone diagram because of its characteristic appearance. According to Čelar et al. (2014) Ishikawa "in his considerations found that there are 6 major groups of causes in the occurrence of errors and called them 6M: machine, method, material, man (man power, mind power), measurements and the environment (Milieu / Mother Nature)."

## 5. Conclusion

Risk cannot be avoided because there is no entrepreneurial activity without risk. Risks

should be taken, but in a planned way. Risk should be accepted as a reality and everything should be done to get to the risk management phase. The risk management system should be a structural element of the management system of the organization as a whole. Risk management is a necessary component of any business organization. With an adequate approach, it reduces potential losses in the long term, which can have disastrous proportions for their further business and even survival. Using ISO / IEC 31010: 2019 risk assessment techniques, such as FMEA method, HACCP method, HAZOP method, Bowtie analysis, brainstorming and many others, it is possible to approach certain threats and danger to the organization and to lay the foundations for the prospective success of crisis avoidance and crisis situations and to better overcome and prepare organization's management in crisis situations. A review of risk management tools and methods discussed in this paper leads to a conclusion that it is very important to make management aware of the need to integrate risk management into the business process in order to identify in time all the risks that could lead to a crisis.

## THE IMPACT OF QUALITY COSTS ON THE LEVEL OF IMS MATURITY

**Abstract:** *The paper presents an overview of the impact of quality costs on the development and implementation of an integrated management System (ISO 9001:2015, ISO 14001:2015, and ISO 45001:2018). Based on the assessment of the current state, the values of scrap and complaints in production business Systems of complex structure were obtained. It is shown how continuous improvements can reduce costs and increase the efficiency of IMS if the causes of their existence are eliminated through improvements. The framework of all three Systems functions on the basis of the PDCA cycle of continuous improvement, which is the key to all three standards. This is another reason that has enabled us to combine three Systems into one Integrated Management System and to increase the maturity level of IMS through improvements.*

**Keywords:** *Business effectiveness, cost efficiency, integrated management System s, international standards, compliance control, process management, management System s, IMS, PDCA*

### 1. Introduction

Integration of management Systems is increasingly being seen as an imperative for optimizing and increasing organizational management efficiency. In today's dynamic environment, the question is not whether management Systems should be integrated, but rather which one is best for a specific organization. Since all organizations are different in terms of their goals and established business culture, it is difficult to develop a single integration model that would meet the requirements of all organizations.

For the success of management integration, it is crucial that the company analyzes the situation and ensures that all involved individuals understand the process before the start of the integration process. This is the

only way in which the implementation of an integrated management System will become an important factor in achieving sustainability and cost reduction.

However, first there needs to be a parallel drawn between the concept of management Systems and the concept of management. It is a misconception that these two concepts are identical. They have the same structure, but different perspectives. The management System only encompasses technical resources, while management also manages human resources, with the goal of achieving performance.

If we focus only on performance, we cannot do business well. The same situation is true for the management process. Isaac Adizes says, "I do not agree with authors whose focus is solely on managing results. It should be managing for results, with appropriate

processes." Primary attention is focused on the goal, but not on the means to achieve that goal. Almost all organizations prioritize financial results as their primary plan. By introducing a quality System into their organizations, many managers think they will solve all problems, including financial ones. Unfortunately, this is not the case, especially in the first years after introducing a quality System, particularly if the quality System is falsely introduced rather than real.

## **2. Correlation between costs and level of IMS**

Performance means achieving specific, measurable results in terms of meeting goals. An efficient management System that supports leadership enables managers to quickly analyze and evaluate achievements or performance in an appropriate form - tailored to their role and responsibility - in accordance with aspects of productivity/profitability, quality, environmental and occupational health and safety. Furthermore, measuring performance in these categories allows a well-founded management assessment of leadership in a pragmatic relationship with specific leadership requirements and established standard requirements.

From an economic perspective, performance focuses on measurements of cost/benefit (productivity, level of performance, yield...) that are suitable for the business model. Goals and measurement parameters need to point towards strategic positioning (cost management, niche positioning, etc.) and orientation. Productivity and quality are closely related according to contemporary understandings of performance. Key performance indicators are considered part of quality indicators. Costs can be shown, but benefits cannot be clearly assigned; therefore, the focus is on cost reduction, not maximizing return on investment.

Observations about the high cost due to a lack of training or personal risks for managers due to non-compliance with legal requirements usually become extremely important only in the case of actual damage. Complaints, waste, environmental damage, and scrap increase the potential for damage, which means that the benefit that arises from consistently applied Integrated Management System is often only visible through potential damage. Figure 1 shows the correlation between the amount of damage (scrap, complaints, rework...) and the maturity level of the Integrated Management System.

## **3. Assessment of the current state**

### **3.1. Methodology for evaluating the current state**

The necessary conditions for a realistic assessment using this methodology are:

- elimination of the subjectivity of the assessor,
- analysis of all processes, activities, and accompanying documentation, and
- direct collaboration and objective relationship between the management and the assessor.

Three business Systems were used for the analysis:

System A is a business System with more than 100 employees. This System has decades of experience in cigarette production, with significant production and personnel resources.

The second characteristic System examined is business System B in the food industry with 80 employees. The System has equipment for the production of juices and oils.

The third characteristic analyzed System is System C in the field of paper packaging

production.

A very small number of companies track quality costs. Quality costs do not solve the problem themselves, but are just a tool that helps management understand the importance of problems in the process. Therefore, it is necessary to solve the problem of collecting data on quality costs and establishing a relationship between total quality costs, external, internal, and prevention costs.

For each subSystem of the observed

companies, a certain number of questions were formulated. Each question was given attributes in the range from "poor" to "excellent", with a real basis for obtaining an appropriate rating of both the entire System and its subSystems, using numerical values from 0 to 10. The rating for each question is recorded in a table as shown in Figure 1. Each question is assigned a certain number of points in advance according to its importance.

**Table 1.** Table for assessing the current state

Grade	Assigning the maximum number of points for a question	Satisfaction assessment	Number of points		
<b>BAD</b>	<b>WEAK</b>	<b>UNCONVINCING</b>	<b>BORDERLINE</b>	<b>CAPABLE</b>	<b>EXCELLENT</b>
0	2	4	6	8	10
0%	20%	40%	60%	80%	100%

After answering questions within a subSystem, the summary table is filled in as in Table 2, with the final evaluation of that

request. Results obtained by testing are presented in Table 3.

**Table 2.** Table for evaluating requests

Assigned maximum number of points	Earned number of points	Satisfaction percentage	Request evaluation

**Table 3.** Table for evaluating requests

<b>External costs</b>			
Name	SYSTEM A	SYSTEM B	SYSTEM C
Complaint costs	6.66	7.68	7.98

Material costs	?	?	?
Other costs	?	?	?
<b>Total</b>	<b>24,5 %</b>	<b>23,35 %</b>	<b>18,4 %</b>

BUSSINES SYSTEM A	91,72 %
BUSSINES SYSTEM B	78,1 %
BUSSINES SYSTEM C	87,4 %

From Table 3 it can be seen that for some costs there is no data, so the values for these costs were estimated. Also, it can be seen from the table that the sum of these costs is not 100%, which means that the costs for which there is no data make up the difference up to 100%. If prevention and assessment costs increase, total quality costs decrease. If the scope of preventive activities increases, total error costs decrease. In order to prevent future nonconformities, it may be necessary to modify the project, development process, production, packaging, transportation, or storage, to revise product specifications or revise the quality SYSTEM.

From Table 4, it is noticeable that a high percentage of quality costs for all business SYSTEM s are due to scrap, rework, and repairs, which means that attention must be

paid to reducing internal and external errors. For such a high percentage of costs, the optimal strategy is investing in preventive activities which significantly reduces the costs of internal and external deficiencies. It is necessary to define which activities must be carried out to achieve the desired improvement, which would correspond to effective and efficient business operations. Obviously, these activities cannot be achieved without strategic quality planning from which improvement projects arise. Activities within the projects must be implemented step by step, because gradual and careful implementation of each step converges to a positive and efficient solution to the problem.

Table 4 provides values for scrap, rework, and complaint costs in percentage and in euros, while Fig. 2 shows a diagrammatic

representation of these costs for all three states. Analysis and reports on quality costs have a purpose only if corrective actions are taken based on them.

Corrective actions can be directed towards:

- eliminating quality deficiencies that are realized by professional services within normal authorization,
- eliminating deficiencies based on quality improvement programs. Corrective measures are used when

deficiencies are of such a nature that their causes are unknown or are only assumed. In this case, a team of experts from various fields should be formed to conduct analyses and identify causes, and then define measures to solve the problem,

- regardless of the corrective action taken, the initiative must come from the management of the company.

**Table 4.** Values of scrap, rework, and complaint costs

	EXISTING STATE	IMPROVEMENT DESIRED	AMOUNT OF CHANGE
Scrap			
System A	36,18% 110760	23,8% 72868	14,28% 43721
Savings		12,38% 37891	21,28% 67039
System B	0	0	0
Savings	0	0	0
System C	31,92% 3050	20 % 1906	13 % 1271
Savings		11,92% 1143	18,92% 1779
Correction			
System A	5,71% 17478	2,85% 8744	2,85 % 1023078
Savings		2,86% 8744	2,85 % 8744
System B	29% 12929	7,69% 3422	5,12% 2281
Savings		21,3% 9507	23,88% 10648
System C	11,92% 289	8% 762	4% 381
Savings		3,92% 381	7,92% 762
Complaints			
System A	6,66% 20403	5,71% 17488	4,27% 8744
Savings		0,95% 2915	3,81% 11659
System B	7,68% 3422	5,98% 2664	4,27% 1901
Savings		1,7% 757	3,41% 1521
System C	7,98% 762	6,66% 635	4,0% 127
Savings		1,32% 127	3,98% 381

Based on the values from Table 4, a diagram in Figure 2 was constructed, where the values for scrap, complaints, and rework costs are graphically represented for all three business SYSTEMS. The results for the case

of improvement and the desired amount of change are also graphically presented. As costs decrease, the maturity level of the IMS increases.

**Figure 1.** Diagram representation of scrap, rework, and complaints costs

## 4. Conclusion

In order to reduce quality costs, it is necessary to apply an effective improvement strategy. This involves focusing on preventive costs and appraisal costs. It has been proven on a concrete example that this approach reduces scrap and rework costs. Integrated management SYSTEM can

represent a very small, but sufficiently large basis for building business excellence, because it enables the organization to gradually shift its focus from customers only to all stakeholders. Integration of management SYSTEMs is crucial if companies want to achieve greater optimization and efficiency in their management.

## EVALUATING SCOR METRICS OF SUPPLY CHAIN PERFORMANCE BASED ON INVENTORY MANAGEMENT

**Abstract:** *Because Supply Chain Performance coordinates Inventory Management under the SCOR Metrics paradigm; this research was performed to evaluate the SCOR Metrics of Supply Chain Performance based on Inventory Management at Shiraz Petrochemical Company of Iran. Performance indicators, as Alternatives; and Inventory Management factors, as criteria; were extracted from the research literature. The research method was descriptive-analytical, employing a hybrid FAHP-SCOR approach. Consequently, after weighing the criteria, the five alternatives have been prioritized. The results of this study lead to two deductions: firstly, the type of production is the most important factor in Inventory Management. Secondly, companies with a complex supply chain need to carry out processes to strike the right balance between the size of their inventory. The findings of this study can be applied to all petrochemical industries as a strategic plan.*

**Keywords:** *Supply Chain Performance, Inventory Management, SCOR, FAHP*

### 1. Introduction

In today's global situation, despite the challenges in supply chain management (SCM), including competition, changing markets, globalization, and balancing supply and demand (Ben-Daya et al., 2022), it is necessary to provide a variety of products according to customer demand. The customer's demand for high-quality service has faced company challenges. Consequently, in today's competitive market, economic, manufacturing, and service enterprises, in addition to managing internal resources, have found themselves in need of managing and monitoring resources and elements outside the organization. This approach is to gain a competitive advantage that companies intend to gain a larger share of the target market (Sigh et al., 2018; Solke et al., 2022; Subramanian and Suresh, 2022).

Accordingly, activities such as dynamic supply and demand planning, material procurement, production planning, logistics, inventory management, distribution, delivery, and just-in-time customer service, which were previously performed at the company level, are now transferred to the value chain level. The basic point in a supply chain is the management and coordination of all these activities; It is such that customers can receive quality products and lean services in the shortest time and at the lowest cost (Tan and Sidhu, 2022).

Many studies have been done on different dimensions of the supply chain inventory (Daryanto and Wee, 2020). Multiple models have been introduced to appraise the supply chain performance. In 1996, the Supply Chain Association introduced the Supply Chain Operations Reference (SCOR) model, which is presented as a standard reference

---

Email: [anvar.ali67@gmail.com](mailto:anvar.ali67@gmail.com)

for SCM. It helps companies increase their supply chain's effectiveness and provides a process-oriented approach to SCM (Huan et al., 2004). As companies move toward SCM, evaluating Supply Chain Performance seems more necessary. Notably, traditional evaluation methods are less related to SCM because the scope they examine is much more limited than examining a wide range of evaluation activities (Ricardianto et al., 2022; Rodríguez Mañay et al., 2022).

From the establishment of Shiraz Petrochemical Company in 1959 until now, the National Iranian Petrochemical Company (NPC), as one of the country's main industries in creating added value from oil and gas resources, has been a pioneering and value-creating industry. This industry plays a crucial role in Iran's financial and economic prosperity, sustainability in development, localization of technology acceptance, growth and development of downstream industries, and creation of full employment. The main advantage of this industry in Iran is the variety of feedstock resources, access to the high seas, and specialized human resources (National Iranian Petrochemical Company, n.d.).

Shiraz Petrochemical Company, the first production unit of NPC, produces nitrogen fertilizers. The company started with the operation of four production units for ammonia, urea, nitric acid, and ammonium nitrate, as well as a unit for providing ancillary services (water, electricity, steam, and compressed air). At present, the effort and importance of the company's management and employees to improve the quality of the work environment have led to obtaining certificates in quality assurance management, environmental management, and professional occupational health and safety management (Shiraz Petrochemical Company, n.d.).

Therefore; in the current unfavorable economic conditions of the country, with the proper knowledge of the market and with the

help of proper SCM, from the purchase of raw materials to sales and after-sales services, and paying attention to the Inventory Management approach of smoothing the supply chain processes (Ben-Daya et al., 2022), it is possible to help the continuity of production and sales in the market. In this field, much research has been done so far, but comprehensive research that deals with the performance of SCM, identifying and ranking essential indicators, and applying a comprehensive approach to performance evaluation in Shiraz Chemical Company has not been done, which adds to the importance and necessity of this research.

Accordingly, in the present research, we intend to evaluate the indicators of Supply Chain Performance based on Inventory Management at Shiraz Petrochemical Company. This research aims to combine FAHP and SCOR in evaluating SCM indicators based on Inventory Management at Shiraz Petrochemical Company of Iran.

## 2. Literature review

### 2.1. Supply chain management

Today, SCM is considered one of the infrastructure bases for implementing electronic business worldwide. In today's global competition, various products should be made available according to the customer's demand (Richey et al., 2022). A short definition of the supply chain is that supply chain management includes all physical and informational activities related to the flow and transformation of products, from raw material extraction to final product delivery (Mentzer et al., 2001). The main processes of sustainable supply chain operation are as follows: information management, logistics management, and communication management.

### 2.2. Information management

Today, the role and position of information are clear to everyone. The correct circulation and transmission of information makes coordinating activities and processes more effective and efficient and simplifies their management (Anand and Goyal, 2009). Correct information management leads to greater coordination in the supply chain. So that more and more appropriate information coordination between partners and different work departments greatly affects speed, accuracy, quality, and other effective aspects. (Yang and Fan, 2016).

### 2.3. Logistics management

In analyzing production and service systems, the logistics issue includes the physical part of the supply chain. This stage includes all physical activities that start from the stage of preparation of raw materials and continue until the delivery of final products. The most important of these activities include production planning, transportation, storage, etcetera, which account for a relatively large part of the effective activities in the supply chain (Soni and Gupta, 2020). This means that the concept of logistics is not only the flow of materials and products but also includes all activities of the supply chain; To the extent that practical information is one of the logistics support tools to improve the activities of that organization (Stock and Lambert, 2001; Buurman, 2002; Durach and Kembro, 2021).

### 2.4. Relationship management:

It is a factor that leads us to the conclusion of literature and discussion. The most important part of SCM in terms of its structure and form is relationship management in the supply chain. Relationship management strongly affects all levels and functional dimensions of the

supply chain (Hingley, 2011). The information systems and technology needed for SCM operations are often easily accessible, and they may be completed and deployed in a rather short amount of time. However, many of the initial failures in the supply chain are due to the lack of optimal planning in the definition and deployment of the chain (Sutthachaidee et al., 2022). In addition, the most important factor for SCM's success is having reliable mutual communication between chain partners. In short, in developing an integrated supply chain, trust and confidence between partners are critical factors for success (Cox, 2004; Meng, 2012).

### 2.5. Inventory Management in the supply chain

Inventory Management in the supply chain is very important in various production and service areas. Among the material flows, which are: financial, informational, and material; Materials are of great importance (Cachon and Fisher, 2000; Singh and Verma, most of Iran's manufacturing and industrial units, the traditional point of view is still used for supply, production, and distribution planning so that each of these plans their activities independently. For this reason, it primarily increases the total costs of the supply chains (Manzouri et al., 2010; Valmohammadi, 2014; Bazaz et al., 2022). In today's daily life, with the increase in the issue of purchasing, the importance of decisions related to purchasing has increased. In most industries, raw materials and utilized parts are the major part of product costs. So more than 50% of the total cost of the products includes purchased materials and services. Therefore, decisions related to adopting strategies in the purchasing chain determine profitability (Weele ,2018). Inventory Management by the seller is a new way of integrating the supply chain, where the supplier is

responsible for controlling and replenishing the retailer's inventory (Sui et al., 2010; Lotfi et al., 2022). The three main criteria of Inventory Management, with their concepts and attributes, based on Eissa and Rashed (2020) and Farmaciawaty et al. (2020), are determined as follows:

- Product with relevant factors (standard product, duplicate product, low demand changes for the product, clarity of the forecasted demand and inventory levels)
- Company with relevant factors (the stability of the company's annual income, high purchase transaction costs, good communication and information systems, sharing forecasted inventory information with the company's suppliers)
- Supplier with relevant factors (high level of trust and long-term relationship with the supplier, benefits of Vendor-Managed Inventory (VMI) implementation for the company and the supplier, key suppliers that have a high percentage of purchase orders, the company's information system association with suppliers)

This article considers an inventory model in a two-level supply chain under the VMI system, including a manufacturer and retailer. This model is formulated to optimize pricing decisions, replenishment amount, and frequency simultaneously to maximize supply chain profits. The retailer's market demand is price-dependent, and the manufacturer sends the manufactured stock to the retailer in several smaller batches to meet the demand. In real production conditions, generally, in addition to non-defective items, defective items are also produced. In this model, the production process is incomplete, and the shortage is not allowed.

## 2.6. SCOR model

The model of SCOR is a reference model and provides a standard and comprehensive model and framework for specifying efficient and effective activities along the supply chain; the main advantage of performance evaluation by this model compared to previous models is the process-oriented perspective of this model (Hasibuan et al., 2018). The SCOR model creates a balance between horizontal (inter-process) and vertical (hierarchy between processes) perspectives, and its use allows organizations to play an important and effective role in improving the overall performance of the chain by using common terminology and standard processes (Poluha, 2007; Kusriani et al., 2019). As a result of this process-oriented view, a hierarchical and structured body of evaluations and criteria is created, which gives a general view of the supply chain to all supply chain managers. Since the SCOR model is one of the suitable examples of process-oriented performance evaluation systems and is a comprehensive and standard model in this field, this research, based on the model and the indicators presented in the first level of the model and research techniques in operations, a model has been presented to evaluate the performance of SCM (Bolstorff and Rosenbaum, 2007). In the following, the five factors of Supply Chain Performance are explained:

**Supply Chain Reliability:** The performance of the supply chain considers the delivery of the necessary products, at the best possible place and time, with optimal conditions, in the necessary quantity, and according to the right documentation to the desired customer (Rombe and Hadi, 2022).

**Supply Chain Responsiveness:** It is the average actual time spent to satisfy the demand (SCOR11:2012).

**Agility of the supply chain:** the agility and flexibility of the supply chain in responding

to market changes to maintain or increase competitive advantages (SCOR11:2012).

**Total supply chain costs:** total supply chain costs spent on delivering products and services to customers (SCOR11:2012).

**The efficiency of asset management:** the use of an organization in asset management to support the satisfaction of demand; this feature includes the management of fixed and variable assets (SCOR11:2012).

## 2.7. The theoretical framework of research

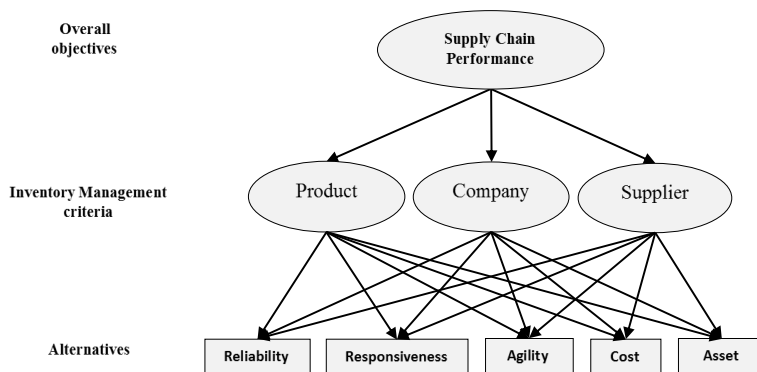

SCM indicators were presented in the 1990s by the Supply Chain Council, based on which SCM was examined in five indicators: Reliability, Responsiveness, Agility, Cost, and Asset (Putra et al., 2022; Rodríguez Mañay et al., 2022). The model, which was

designed based on the business process, examines all supply chain activities according to the five mentioned indicators (Thunberg and Persson, 2014; Maestrini et al., 2015; Balfaiah et al., 2016).

Moreover, as stated in paragraph 2.2 of the research literature; the factors of Inventory Management (Eissa and Rashed, 2020; Farmaciawaty et al., 2020) have been determined by the following three factors:

- Product with a number of sub-criteria
- Company with a number of sub-criteria
- Supplier with a number of sub-criteria

The present research will examine SCM criteria based on the five main criteria of the SCOR model, presented in Figure 1.

**Figure 1.** Proposed FAHP Model for SCOR Metrics of SCP based on Inventory Management

## 3. Research method

A descriptive-analytical research method was used to evaluate SCM indicators based on Inventory Management with the combined approach of SCOR and FAHP. Based on the SCOR model, the indicators are divided into five alternatives: Reliability, Responsiveness, Agility, Cost, and Asset. Three criteria of product, supplier, and company were considered for Inventory

Management, and the results were analyzed based on the pairwise comparison questionnaire provided to 15 experts. After data collection, the research's reliability was checked, consistent, and suitable for analysis. In the following, during quantitative operations, Inventory Management factors as criteria; and Supply Chain Performance factors as alternatives; are ranked. A schematic diagram of the steps mentioned above is shown in Figure 2.

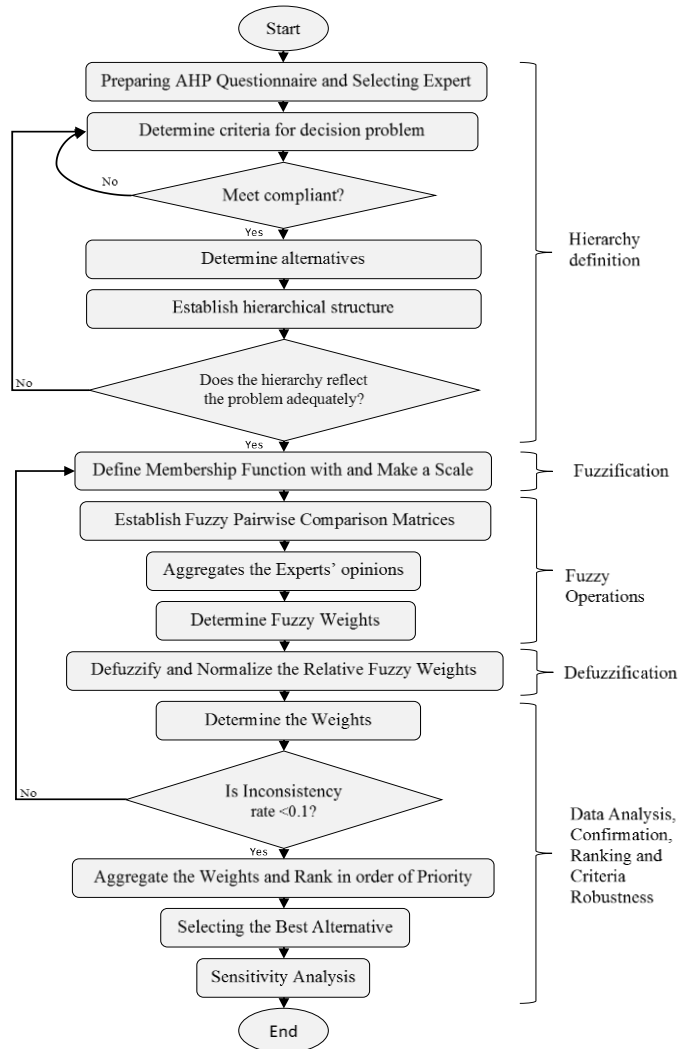

Figure 2. Fuzzy AHP flowchart

### 3.1. Analytical Hierarchy Process

Analytic Hierarchy Process (AHP) is a measurement method used to prioritize homogeneous elements through pairwise comparisons and heterogeneous elements through clustering (Saaty, 1994), which helps the decision maker to make decisions

with subjective and conflicting criteria. AHP is mainly used in the following cases; when the problem analysis shows that it should be broken into its constituent elements and When there is a hierarchy of constituent elements about the goal (Saaty, 1988).

### 3.2. Fuzzy AHP (FAHP)

The hierarchical analysis process method deals with hierarchically prioritizing options. However, many researchers have created ambiguities in the correctness of this method and have stated that this method cannot correctly show the decision maker's opinion and considering it is not certain that pairwise comparisons are made subjectively. For this reason, decision-makers can use fuzzy numbers instead of definite numbers in pairwise comparisons. Fuzzy numbers are used in the fuzzy hierarchical analysis process to perform pairwise comparisons (Sun et al., 2010; Chan et al., 2019).

#### Step 1 - Construct the hierarchy structure model

At this stage, decision-makers with relevant knowledge and experience are selected to assist in the work process, like preparing a standard questionnaire and determining criteria and alternatives to construct a hierarchical process.

#### Step 2 - Fuzzification

In the current study, Triangular Fuzzy Numbers (TFNs) were used to decrease ambiguity and uncertainty for pairwise comparison. In triangular fuzzy, numbers are represented with three points in the interval

$(0,1) \tilde{A} = (l, m, u)$ , represented in Figure 3. Where  $a$  and  $c$  represent the smallest and largest number of the set and  $b$  is the mid-value. Equation (1) shows the membership function of TFNs.

$$\mu(\tilde{A}) = \begin{cases} \frac{x-l}{m-l} & l \leq x \leq m \\ \frac{u-x}{u-m} & m \leq x \leq u \\ 0 & \text{Otherwise} \end{cases} \quad (1)$$

**Figure 3.** The membership function of TFNs

#### Step 3 - Fuzzy Operations

In this article, 9-point TFNs ( $\tilde{1}, \tilde{2}, \tilde{3}, \dots, \tilde{9}$ ) are used for constructing a pairwise comparison matrix. The 9 TFNs are defined with the related triangular fuzzy sets, as shown in Figure 4 and Table 1 (Saaty, 2000).

**Figure 4.** The membership functions of TFNs (linguistic values) ( $\tilde{1}, \tilde{2}, \tilde{3}, \dots, \tilde{9}$ )

**Table 1.** Definition and membership function of Linguistic Terms

Intensity of importance	Fuzzy number	Definition	Explanation	Scale of Fuzzy number	Inverse Fuzzy equivalent
1	$\bar{1}$	Equally important	Two attributes contribute equally	(1, 1, 1)	(1, 1, 1)
2	$\bar{2}$	Weak advantage	Equally to moderately more important	(1, 2, 3)	(0.333, 0.5, 1)
3	$\bar{3}$	Not bad	Experience and judgment slightly favor one activity over another	(2, 3, 4)	(0.25, 0.333, 0.5)
4	$\bar{4}$	Preferable	Moderately to strongly important	(3, 4, 5)	(0.2, 0.25, 0.333)
5	$\bar{5}$	Good	Experience and judgment strongly favor one activity over another	(4, 5, 6)	(0.166, 0.2, 0.25)
6	$\bar{6}$	Fairly good	Strongly to very strongly more important	(5, 6, 7)	(0.142, 0.16, 0.2)
7	$\bar{7}$	Very good	An activity is favored very strongly over another; its dominance demonstrated in practice	(6, 7, 8)	(0.125, 0.142, 0.166)
8	$\bar{8}$	Absolute	Very strongly to extremely more important	(7, 8, 9)	(0.111, 0.125, 0.142)
9	$\bar{9}$	Perfect	The strongest potential order of affirmation exists for indicating that one activity is preferable to another.	(8, 9, 10)	(0.1, 0.111, 0.125)
<b>Reciprocals</b>			Reciprocals for inverse comparison		

Next, the Fuzzy reciprocal judgment matrix, using TFNs, is established as Equation (2):

$$\tilde{A} = \begin{bmatrix} 1 & \tilde{a}_{12} & \dots & \tilde{a}_{1n} \\ \tilde{a}_{21} & 1 & \dots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \dots & 1 \end{bmatrix} \quad (2)$$

After aggregating experts' opinions, geometric mean was used to determine the fuzzy weights of matrices. Equations (3) and (4) are suggested by Buckley (1985) to use fuzzy geometric mean and fuzzy weight, respectively.

$$\tilde{r}_i = \left( \prod_{j=1}^n \tilde{a}_{ij} \right)^{\frac{1}{n}} \quad (3)$$

$$w_i = \tilde{r}_i / (\tilde{r}_1 + \dots + \tilde{r}_n)^{-1} \quad (4)$$

**Step - 3 Defuzzification**

At this stage, the obtained weight has been converted into a crisp real number. Several methods are available, e.g., mean of maximum, center of area, cut method, and Sugeno defuzzification method (Zhao and Govind, 1991; Guney and Sarikaya, 2009). In this present study, Sugeno defuzzification

method is used to obtain output crisp real numbers. In order to obtain a crisp value, each input is multiplied by a constant and added up to the result to make equations called 'rules of strength' or 'degree of applicability' and finally mathematically combine these equations, which is the weighted average of all rule outputs (Sugeno and Tanaka, 1991; Mendis et al., 2020). The defuzzified value of the fuzzy number is computed using Equation (5).

$$W_{\text{crisp}} = \frac{\sum_{i=1}^n w_i z_i}{\sum_{i=1}^n w_i} \quad (5)$$

**Step - 4 Data Analysis, confirmation, ranking, and criteria Robustness**

Normalization of crisp real numbers is conducted using Equation (6).

$$n_{ij} = \frac{a_{ij}}{\sum_{i=1}^n a_{ij}} \quad (6)$$

The consistency of the decision problem is examined in two aspects; 1) The variables and criteria that are compared should be related and of the same type, and 2) The

consistency ratio of pairwise comparison judgments is investigated. The inconsistency index (II) and inconsistency rate (IR) are calculated using Equations (7) and (8), respectively. Where  $\lambda_{max}$  is the largest eigenvalue of the comparison matrix, n is the dimension of the matrix, and the

inconsistency index of the random matrix (IIR) is selected from Table 2 (Saaty,1994; Saaty, 2000; Kwong and Bai, 2010).

$$II = \frac{\lambda_{max}-n}{n-1} \tag{7}$$

$$IR = \frac{II}{IIR} \tag{8}$$

**Table 2.** Inconsistency index of the random matrix

N	1	2	3	4	5	6	7	8	9	10
<b>IIR</b>	0	0	0.52	0.39	1.11	1.25	1.35	1.40	1.45	1.49

If the IIR value is less than 0.1, the comparisons are acceptable, and variables can be ranked; otherwise, decision-makers must revise the original values in a pairwise comparison matrix. At last, to investigate the robustness of the criteria, sensitive analysis is applied by switching the weight of the criteria.

### 3.3. Data Analysis

This research aimed to evaluate Supply Chain Performance based on Inventory Management. Data analysis has been done in two stages: the first stage, Pairwise

comparisons of the triple factors of Inventory Management, and the second stage, Pairwise comparisons of five SCOR indices based on Inventory Management criteria.

**Step 1** - Pairwise comparisons of the three criteria of Inventory Management (product, company, supplier).

After preparing the pairwise comparison questionnaire and obtaining SCOR through 15 experts in the industry, Aggregation of questionnaires (using the geometric mean method) and fuzzy transformation were done (Table 3).

**Table 3.** Aggregation of experts' opinions of criteria (geometric mean)

Inventory Management	Product (C1)			Company (C2)			Supplier (C3)		
<b>Supplier (C3)</b>	1.00	1.00	1.00	1.70	2.80	3.85	0.71	1.07	1.65
<b>Supplier (C3)</b>	0.25	0.33	0.52	1.00	1.00	1.00	0.43	0.63	0.83
<b>Supplier (C3)</b>	0.66	1.05	1.68	1.52	2.15	3.14	1.00	1.00	1.00

As evident in Table 3, all the fuzzy numbers of the aggregated questionnaire of the experts in the pairwise comparison of Inventory Management factors have been calculated through the geometric mean. The fuzzy weights of Inventory Management factors are shown in Table 4.

As evident in Table 3, all the fuzzy numbers of the aggregated questionnaire of the experts in the pairwise comparison of Inventory Management factors have been calculated through the geometric mean. The fuzzy weights of Inventory Management factors are shown in Table 4.

**Table 4.** Final weights of Inventory Management factors

Criteria	Final weight	Normal weight	Rank
Product	0.4587	0.427	1
Company	0.1905	0.177	3
Supplier	0.4248	0.396	2

Based on Table 4, in pairwise comparisons of Inventory Management criteria, the product criterion with the highest weight, is in the first place, and supplier and company criteria are ranked second and third, respectively.

**Step 2** - Pairwise comparisons of SCM indicators. The SCOR ranking (Reliability, Responsiveness, Agility, Cost, and Asset) is based on the criteria of Inventory Management (product, company, supplier) presented in Table 5.

**Table 5.** SCOR factors (alternatives) ranking based on Inventory Management criteria

Criteria	Reliability (A1)	Responsiveness (A2)	Agility (A3)	Cost (A4)	Asset (A5)
Reliability (A1)					
Responsiveness (A2)					
Agility (A3)					
Cost (A4)					
Asset (A5)					

Based on this model, pairwise comparisons of 5 alternatives (Supply Chain Performance indicators) are performed in three stages based on three Inventory Management criteria (product, company, supplier) separately. Carrying out this process for each of the criteria is in four steps:

1. Pairwise comparisons alternatives based on criteria
2. Geometric mean of Alternatives based on criteria

3. Fuzzy weights of Alternatives based on criteria
4. Final weights of Alternatives based on criteria

**Ranking alternatives based on product:** Criteria Aggregated experts' opinions of pairwise comparison of alternatives based on product criteria (geometric mean) are shown in Table 6.

**Table 6.** Pairwise comparison alternatives based on product criteria

Product Criteria	A1		A2		A3		A4		A5						
A1	1.00	1.00	1.00	0.34	0.50	0.80	0.26	0.35	0.56	2.49	3.59	4.64	1.52	2.27	3.25
A2	1.25	2.00	2.96	1.00	1.00	1.00	0.33	0.50	1.00	3.18	4.36	5.45	2.64	3.68	4.70
A3	1.78	2.86	3.90	1.00	2.00	3.00	1.00	1.00	1.00	5.16	6.21	7.24	4.08	5.10	6.12
A4	0.22	0.28	0.40	0.18	0.23	0.31	0.14	0.16	0.19	1.00	1.00	1.00	0.33	0.50	1.00
A5	0.31	0.44	0.66	0.21	0.27	0.38	0.16	0.20	0.25	1.00	2.00	3.00	1.00	1.00	1.00

As evident in Table 6, all the fuzzy numbers of the aggregated questionnaire of the experts in the pairwise comparison of the Supply Chain Performance alternatives based on the criteria of the products (inventory) have been calculated through the geometric mean, and the numbers of the main diameter are all one. The numbers below the main diameter are the inverse numbers above the main diameter. After

determining the IR (less than 0.1), the questionnaires are consistent according to Table 6 and are suitable for analysis. In the following, the fuzzy weights of the Supply Chain Performance alternatives based on the product criteria are given in Tables 7 and 8.

The final weights of SCM **alternatives** based on product criteria are shown in Table 9.

**Table 7.** The geometric mean of Alternatives based on product criteria

Product Criteria	l	m	u
A1	0.8000	1.0732	1.4664
A2	1.2833	1.7418	2.3761
A3	2.0649	2.8293	3.4903
A4	0.2831	0.3486	0.4761
A5	0.4036	0.5425	0.7128
Sum of averages	4.8348	6.5353	8.5218
The inverse of the total	0.1173	0.1530	0.2068

**Table 8.** Fuzzy weights of Alternatives based on product criteria

Product Criteria	l	m	u
A1	0.09387	0.16422	0.30331
A2	0.15059	0.26651	0.49146
A3	0.24231	0.43293	0.72191
A4	0.03322	0.05333	0.09847
A5	0.04736	0.083	0.14744

**Table 9.** Final weights of Alternatives based on product criteria

Product Criteria	Final weight	Normal weight	Rank
A1	0.181	0.168	3
A2	0.294	0.271	2
A3	0.458	0.423	1
A4	0.060	0.055	5
A5	0.090	0.083	4

According to Table 9, the final ranking of Supply Chain Performance **alternatives** based on the criterion of the product will be as follows: 1-Agility, 2-Responsiveness, 3-Reliability, 4-Asset, 5-Cost.

**Ranking alternatives based on Company:**

Pairwise comparisons of Supply Chain Performance **alternatives** based on the company criteria. Due to the repetition of the work steps of evaluating the alternatives based on different criteria, only the first and

last tables have been given.

Based on the numbers obtained in Table 10, it is clear that all the fuzzy numbers of the aggregated questionnaire of the experts in the pairwise comparison of the Supply Chain Performance **alternatives** were calculated based on the company criteria (inventory) through the geometric mean, and the numbers below the main diameter are inversed numbers above the main diameter.

In the following, after calculating of

“Geometric mean” and “Fuzzy weights” of Alternatives based on Company criteria, the Final weights of Alternatives based on Company criteria are calculated in Table 11. In the following, after calculating the

“geometric mean” and “fuzzy weight” of the alternative options based on the company criteria, the final weights of the alternatives based on the company criteria are calculated in Table 11.

**Table 10.** Pairwise comparison alternatives based on company criteria

Company criteria	A1		A2		A3		A4		A5						
A1	1.00	1.00	1.00	1.10	1.68	2.30	0.58	1.00	1.55	2.49	3.59	4.64	1.89	2.61	3.59
A2	0.44	0.59	0.91	1.00	1.00	1.00	0.30	0.43	0.76	1.43	2.57	3.65	1.52	2.55	3.57
A3	0.64	1.00	1.72	1.32	2.35	3.37	1.00	1.00	1.00	2.79	3.87	4.92	1.72	2.86	3.94
A4	0.22	0.28	0.40	0.27	0.39	0.70	0.20	0.26	0.36	1.00	1.00	1.00	0.33	0.50	1.00
A5	0.28	0.38	0.53	0.28	0.39	0.66	0.25	0.35	0.58	1.00	2.00	3.00	1.00	1.00	1.00

**Table 11.** Final weights of Alternatives based on Company criteria

Company criteria	Final weight	Normal weight	rank
A1	0.325	0.293	2
A2	0.213	0.192	3
A3	0.362	0.326	1
A4	0.085	0.077	5
A5	0.124	0.112	4

According to the results from the company criteria, agility is more important, and reliability is ranked second.

**Ranking alternatives based on supplier:** Pairwise comparisons of Supply Chain

Performance **alternatives** based on supplier criteria. Due to the repetition of the work steps of evaluating the alternatives based on different criteria, only the first and last tables have been given.

**Table 12.** Pairwise comparison alternatives based on supplier criteria

Supplier criteria	A1		A2		A3		A4		A5						
A1	1.00	1.00	1.00	1.32	2.35	3.37	3.32	4.34	5.35	3.57	4.57	5.58	3.44	4.48	5.50
A2	0.25	0.33	0.50	1.00	1.00	1.00	2.00	3.00	4.00	3.00	4.00	5.00	2.86	3.90	4.92
A3	0.33	0.50	1.00	1.00	2.00	3.00	1.00	1.00	1.00	1.15	2.17	3.18	0.80	1.52	2.41
A4	0.20	0.25	0.33	0.33	0.50	1.00	0.25	0.33	0.50	1.00	1.00	1.00	0.33	0.50	1.00
A5	0.25	0.33	0.50	0.25	0.33	0.50	0.33	0.50	1.00	1.00	2.00	3.00	1.00	1.00	1.00

Based on the numbers obtained in table 12, it is clear that all the fuzzy numbers of the aggregated questionnaire of the experts in the pairwise comparison of the Supply Chain Performance **alternatives** were calculated based on the criteria of the supplier (inventory) through the geometric mean, and the numbers below the main diameter are inversed numbers above the main diameter. After determining the IR (less than 0.1), the questionnaires are consistent according to

Table 12 and are suitable for analysis. In the following, after calculating the “geometric mean” and “fuzzy weight” of the alternative options based on the company criteria, the final weights of the alternatives based on the Supplier criteria are calculated in Table 13.

According to Table 13, the final ranking of the Supply Chain Performance **alternatives** based on the criteria of the supplier will be as follows: 1- Reliability 2- Responsiveness 3- Agility 4- Asset 5- Cost.

**Table 13.** Final weights of Alternatives based on Supplier criteria

Supplier criteria	Final weight	Normal weight	rank
A1	0.439	0.404	1
A2	0.265	0.244	2
A3	0.202	0.186	3
A4	0.076	0.070	5
A5	0.104	0.096	4

**Determining the normal weights of the alternatives:** The final weight of each alternative should be normalized once weights are determined based on criteria, and these weights will be taken into account when determining the final rank of each criterion.

The ranking of SCM alternatives based on Inventory Management is given in Table 14. After calculating the weights of SCM based

on inventory alternatives, in the last step, the final matrix of the obtained weights should be calculated, and the final results should be considered as the final rank of each alternative in the SCOR model.

According to Table 15, the final ranking of alternatives based on Inventory Management will be as follows; Agility, Reliability, Responsiveness, Asset, and Cost, as illustrated in Figure 5.

**Table 14.** Final ranking of Alternatives based on criteria

	A1	A2	A3	A4	A5
C1	3	2	1	5	4
C2	2	3	1	5	4
C3	1	2	3	5	4

**Table 15.** Final ranking matrix of Alternatives

#### 4. Sensitivity analysis

Sensitivity analysis is used to determine independent parameters' effect on dependent parameters. The outcome is determined by varying the independent variables over a predetermined range (Sachan and Datta, 2005; Anand et al., 2019). Sensitivity analysis demonstrates the degree to which a result depends on a particular variable. The results are sensitive if the ranking order is altered by elevating or lowering the weight of the criteria; otherwise, it is robust (Senthil et al., 2014).

By varying the weights of two criteria, which resulted in three scenarios, various scenarios were represented to investigate the impact of weights on selecting five alternatives. The weights of criteria 1 and 2 are switched in each experiment as indicated by the C12 symbol, which denotes the weight switch. Table 16 and Figure 6 present the sensitivity analysis results, showing that A3 scored highest twice and A1 ranked first once in the three experiments. The outcome demonstrates the robustness and low sensitivity of the criteria. As a result, the decision-making process rarely responds to the weight of the criteria.

**Table 16.** Results of sensitivity analysis

Scenario No.	Experiment No.	A1	A2	A3	A4	A5
1	C12	0.31468576	0.22673465	0.28787291	0.07033269	0.10037149
2	C23	0.29061455	0.24568992	0.30466201	0.06536453	0.09367118
3	C13	0.25908969	0.23517543	0.34263508	0.06634278	0.09675733

**Figure 6.** Sensitivity analysis in a radar chart.

#### 5. Discussion and Conclusion

Based on the presented model, the evaluation of **SCOR Metrics of Supply Chain Performance** indicators based on Inventory Management with the hybrid approach of FAHP and SCOR was discussed in Iran

Petrochemical Company. Based on the SCOR model, the indicators are divided into five **alternatives**: Reliability, Responsiveness, Agility, Cost, and Asset, and three criteria of product, supplier, and company are considered for Inventory Management. The designed questionnaire

given to 15 experts at Iran Petrochemical Company served as the basis for analyzing the results. The improved FAHP technique was initially employed as the best technique for problem-solving. The IR, based on which all 15 research questionnaires and the obtained cumulative matrices were deemed consistent and appropriate for analysis, was also checked to determine the reliability of the research. The **alternatives** and the final rank on each scale were studied further to produce the results shown below:

**Ranking of Inventory Management criteria:** Product-related factors received the top ranking in this comparison, followed by supplier-related factors in second place and company-related factors in third place. There has not been any comparable study in this area to compare. However, given that the product's contributing factors include: standard products (minimum customization of the products), repetitive products (small changes made by the customer), low demand changes for the products, clarity of forecasted demand, and inventory levels, it is concluded that when choosing petrochemical company products, it is important to keep the following in mind:

- Selecting the type of products produced according to the market
- Raising the standard level of the products according to foreign samples
- Proper and accurate forecasting of the target market and products demand

Based on the results obtained in this research, it seems that SCM that is based on inventory, the importance of product criteria depicts that the supply chain approach based on customer orientation and customer satisfaction is very significant and creates value for customers in manufacturing companies, creating value for customers can be the most critical function for the supply chain.

**The results of the final ranking of the SCOR Metrics of Supply Chain Performance:** In general, Supply Chain Performance indicators were presented by the Supply Chain Council in the 1990s, based on which SCM was evaluated based on five **alternatives** of Reliability, Responsiveness, Agility, Cost and Asset. Based on this, this model, designed based on the business process, examines all supply chain activities based on the five mentioned indicators (Sellitto et al., 2015). The following are the final rankings for SCM based on inventory management: Agility, Reliability, Responsiveness, Asset, and Cost. The most important indicator in this regard was organizational agility and reliability, and it shows that the petrochemical company should use all available tools for agility and reliability strategies.

Guritno et al. (2015), in similar research to the evaluation of supply chain factors and classification of Inventory Management at the level of fresh vegetable suppliers based on the SCOR reference model, showed that the most efficient indicator was cost. In a similar research, the results of Hasibuan et al. (2018) research in "Performance analysis of SCM" indicate the prioritization of five performance criteria of the supply chain as follows: Responsiveness, Agility, Reliability, Asset, and Cost. The above research results are precisely the same as the present research. Praharsi et al. (2021), in a research field of "Supply Chain Performance," showed that the lowest performance metric value is the cost of goods. But in Kusriani et al. (2019). "Supply Chain Performance Measurement" research, agility ranked last. The reasons for the different results can be things like: type of industry, type of organization, type of country, type of product, et cetera. Ambe's (2014) research findings showed that the reliability and quality of the final products are the most significant indicators of South Africa's light vehicle market.

Although the purpose of SCM is to ensure that the products are delivered at the right place and time through inventory optimization, it can be seen that the importance of the five factors (Reliability, Responsiveness, Agility, Cost, and Asset) is different according to the type of company. Therefore, a single result cannot be prescribed.

According to the current research results, since organizational agility and reliability are ranked first and second, prioritization results indicated that human, organizational, technical, and technological factors and strategic factors in terms of organizational agility and reliability should be prioritized for improvement and upgrade. In fact, by training and creating capable and multi-skilled employees, quick response, continuous feedback; agility, and reliability are gained to make it possible to make a decision about the appropriate amount of inventory for each of these levels and help in determining the minimum inventory needed to face uncertainty and products and supply chain problems.

- As a result; Considering the ranking and importance of agility, reliability, and responsiveness, it is recommended to observe the

following points in petrochemical company:

- It is suggested that an aggregated information system be formed from suppliers, and all purchases, inputs, and outputs of the company are made based on determining the order point of stock in products and products. The advantage of this becomes essential since all the raw materials of the factory have expiration dates, and sometimes the lack of proper forecasts causes damage to materials and products;
- Developing standard products and creating forecasted demand;
- Improving the level of high trust and long-term relationship with the supplier, the connection of the company's information system with the suppliers;
- Determining critical points and solving challenges and agility obstacles in the organization;
- Defining reliability engineering in the organization and providing the appropriate policy;
- Drawing a detailed process to respond to all requests (customers, market, and suppliers).

## IMPACT OF GLOBAL CRISIS ON SUPPLY CHAIN MANAGEMENT QUALITY: CASE STUDIES

**Abstract:** *Once the pandemic was brought under control in February 2022, the ongoing conflict between Russia and Ukraine started, which has additionally affected the operations of a number of companies and a number of countries as well. Supply chain interruption poses a risk for companies with long-term impacts, particularly in a highly globalized era in which companies tend to have long and complex chains. The poor preparedness of companies, with no alternative solutions, has brought changes in business processes and supply chains worldwide. The ways the global crisis caused by COVID and the war in Ukraine impacted the supply chains and the business process modifications in domestic companies, will be demonstrated by two case studies: Defining the criteria for supplier selection on the national market and Comparative analysis of exporting the same product by a manufacturer in the automotive industry before and during the global crisis*

**Keywords:** *Supply change management, suppliers, production companies*

### 1. Introduction

The global pandemic caused by COVID-19, declared at the beginning of 2020, initiated significant changes in both society and business. In a very short period, market conditions and business models, as well as many other factors, with digitalization being the one that stood out the most and the one that has become increasingly important in modern business, drastically changed. Business organizations had to adjust rapidly to the newly emerging circumstances, so that they could adapt to the radical changes that were taking place. Once the pandemic was brought under control in February 2022, the ongoing conflicts between Russia and Ukraine began, which has additionally affected the operations of a number of companies and a number of countries. The

increased uncertainty on a global level forced both large and smaller companies to find alternative solutions in terms of trading partners and become even more aware of the significance regarding the source of raw material, component and other production and service material stocks. It is evident that today's companies, through successful cooperations with suppliers and other actors in supply chains, can achieve certain benefits that often result in significant savings, which on the other hand is one of the goals every company strives to achieve. Supply chain interruption poses the risk that can have a long-term effect, particularly in a highly globalized era in which most companies have long and complex chains. The poor preparedness of companies, with no alternative solutions, has brought changes in business processes and supply chains

worldwide. Closing borders led to the disruption in the structure of multinational companies, due to the fact that there were a number of problems during not only the production process, but also the supply chain and logistics. All these factors led to the collapse of the global economy and the establishment of predominantly national companies. Therefore, the supply chain in which the goods, processes and structures can easily be replaced needs to be foreseen as a response to changing condition (Zekhnini, K., et al., 2020). These changing conditions and disruptions bear significant negative consequences on sales return, profit, share yield, brand image, recruitment in companies, customer safety and the total supply chain impact (Chovdhuri et al., 2019; Elliott et al., 2019; Paul, S. K., & Chowdhury, P., 2021).

This paper aims at reviewing the impacts of the global crisis caused by COVID 19 and the war in Ukraine on supply chains and business process modifications in domestic companies providing two case studies as examples: Defining the criteria for supplier selection on the national market and Comparative analysis of exporting the same product by a manufacturer in automotive industry before and during the global crisis.

The first study deals with the analysis of the delayed raw material delivery caused by the closure of borders due to the COVID 19 pandemic, which resulted in the failure to comply with the production deadlines and therefore with the deadlines for the delivery of a final product to its customer. All the above forced companies to seek raw material suppliers on the domestic market.

The second study deals with the analysis of the observed period from 2020 to 2022, in which the total business interruption occurred, followed by the reduced scope of business in the analyzed manufacturing company. For research purposes, the comparison of the reference unit export in 2022 and the export carried out in 2018 has

been demonstrated.

## 2. Supply chains

Supply chain management (SCM) has broadly been defined as the “systematic, strategic coordination of the traditional business functions and tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole” (Payán-Sánchez, B. et al.; 2021, Mentzer et al., 2001, str. 18).

Supply chain is an integrated system that starts from raw material or semi-finished goods, continues with the production, packaging, storing goods and their distribution, and finishes with the delivery of the final product to the end customer (Toygur, A., & Yildirim, U., 2023). The relations within the chain are not limited only to manufacturers and suppliers. There are a number of various parties across the supply chain such as service and logistics providers, retailers, insurance companies, customs brokers and customers (Cooper et al., 1997; Min & Zhou, 2002; Chopra & Meindl, 2007; Toygar, A., & Yildirim, U., 2023.).

Supply chains are the processes you use to deliver your product to customers. The chain encompasses everything, from obtaining the raw material necessary for your product manufacturing to its delivery to the customer (R.Ray, 2009.). A supply chain is the network of all the individuals, organizations, resources, activities and technology involved in the creation and sale of a product. A supply chain encompasses everything from the delivery of source materials from the supplier to the manufacturer to its eventual delivery to the end user.

The supply chain activities imply the transformation of natural resources, raw

material and components into a final product and its delivery to the end user. Supply chain management is the essence of business since it is one of the important added values of trading companies, in which a product is transferred from its place of origin (Manufacturer) or other source (Supplier) to its place of consumption (Buyer).

### 2.1. Production Company Supply Chains

Supply chain is characterized by the flow of material and information within and between the business subjects including suppliers, manufacturers and buyers. The ultimate goal of supply chain management is to satisfy customer requirements in a more efficient manner. For a production company, the goal is to create the right product, for the right customer, in the right amount and at the right time (Wang, G., et al., 2005). This requires carefully devised supply chains.

A manufacturer obtains raw material and components for final goods production from its suppliers. The material may be delivered directly to the factory or they may be handed to an external warehouse where they are consolidated and only then delivered to the factory. The material is processed in the factory, converted into a final product, and then packaged and eventually delivered to warehouses and distribution centers from which the goods are delivered to end users.

The supply chain concept refers to the flow of material (Picture 1):

- 1) from the source (supplier) to the warehouse, from the warehouse to the company (manufacturer); within the company, to the place it is needed; from the company-manufacturer (factory) to the distributor-trader; to the end user (customer)
- 2) from the source (supplier) to the company (manufacturer); within the company to the place where it is needed; from the company-

manufacturer (factory) to the end user (customer)

- 3) from the source to the company (manufacturer); within the company to the place where it is needed; from the company-manufacturer (factory) to the end user (customer)

A typical production supply chain includes the following processes:

- The inbound supply chain that includes: sources, incoming quality control, inbound transportation from the supplier to the production unit, import documentation / customs processes in case the material is imported, receipt of goods and their storage, the management of production raw material stocks;
- The production and internal processes that include: production planning, timetable and production, quality control process, inventory management during the work process, plant maintenance;
- The outbound supply chain/distribution that includes: outbound transportation, final goods quality control, final goods storage in the company factory, external storages and distribution centers, packaging, problems with goods, final product inventory management;
- Customer service that includes: defining the level of services for customers, order management, return management, packaging, defining the distribution channels, product development;
- Other supply management functions that include: backup logistics, supply chain exception management, outsourcing logistics (which is usually conducted at the company headquarters);

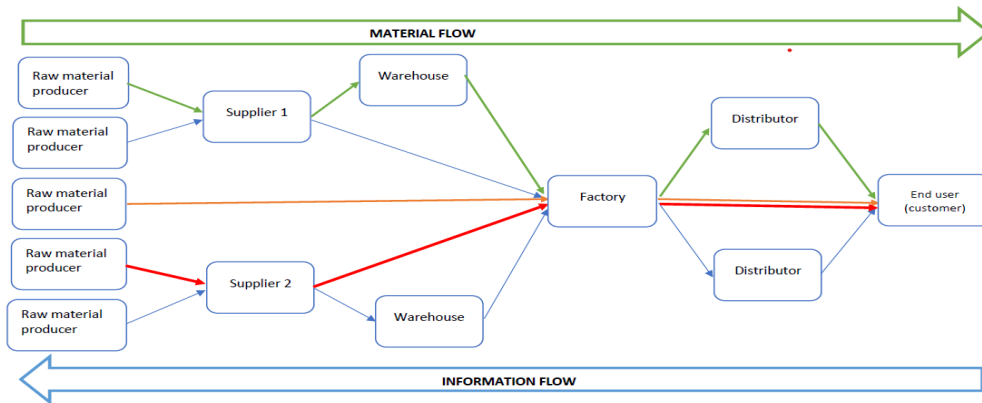

Figure 1. Possible material flow in supply chains

## 2.2. Supply Chain Participants – Suppliers

A supply chain additionally encompasses production and supply. Therefore, it has a significantly wider focus since it includes a number of businesses (including suppliers, manufacturers and traders) that work together in order to satisfy the user requirements for a product or a service.

According to (Hugos, M. H., 2018), there are four types of participants in every supply chain. They perform the activities that make the supply chain work and give the reason for its existence. These participants are: 1) producers; 2) distributors or wholesalers; 3) retailers; and 4) customers or consumers.

If we observe supply chains through their simplest form, we may say that it consists of a company, its suppliers and customers. By combining these actors (supplier, company, customer) we obtain a simple supply chain.

Companies today have become aware that successful cooperation with suppliers can lead to certain benefits that often result in significant savings, which is one of the goals that every company strives to achieve.

According to the definition (Akamp and Muller, 2013) supply relationship management (SRM) is the practice of planning, implementing, developing and

monitoring the relationship of a company with both current and potential suppliers. The key supplier management activities are the selection and evaluation of suppliers, their monitoring, development and integration.

According to (R. Ray, 2009.), supplier relationship management is the key factor that includes all the processes that refer to supply management such as supply planning and execution, source analytics, the selection of suppliers, monitoring their performance, the cooperation with suppliers and all other processes that enable analyzing, controlling and optimizing a source.

Suppliers are an integral part of every business, production in particular. The selection of suppliers is the process of finding the right supplier for business, which includes the steps taken for a supplier discovery, selection and cooperation with them. If we talk about a product quality or its success, the supplier selection is an essential part, since the process of selecting the right supplier is the crucial one.

There are many different types of criteria used for supplier selection. They include price, quality, service, delivery, reputation etc. Certain companies will use all these criteria, whereas some may focus only on one or two of them.

### 3. Case study

#### 3.1. Defining the Criteria for Supplier Selection on the National Market

This part of the paper will demonstrate a case study that analyzes a company which, like most companies in Serbia, was not ready for the challenges in supply chain caused by the global pandemic. The analysis deals with the delay in the raw material delivery caused by the closure of borders due to the COVID 19 pandemic and the consequent inability to import the raw material, which led to a non-compliance with the production deadlines, and therefore with the deadlines to the final product delivery to its customers. All the above forced the company to seek a raw material supplier on the domestic market.

The case study analyzes the company that produces rubber technical goods, including the production of semi-pneumatic wheels, rubber rollers, metal rims, plastic mass and silicon products, compression pressure, injection and die-cutting technologies. The accent is on the semi-pneumatic wheels for agricultural machinery. The company had imported the raw material from Slovenia and Austria until 2020, when the COVID 19 pandemic began, causing the closure of borders, which led to the production decline and the drop in the final product export to the foreign market in the following months, since the company exports more than 90% of the wheels to the foreign market (Germany, Russia, Austria, etc.).

The company values and selects its suppliers based on their ability to meet the requirements from the agreement/specification, including the requirements that refer to the quality management system, as well as any other specific quality requirement.

The Procurement Officer along with his or her team defines the criteria and the method of the evaluation and selection of suppliers

that include the suppliers of raw material, material and components, as well as service providers – external providers, in order to create the “List of Verified Suppliers”, with the goal to ensure adequate reliability with respect to harmonizing the procurement of material and goods or the contracted service with the agreement/specification requirements, including the requirements that refer to quality management system.

The basic criteria for supplier rating are: quality control, certificate of analysis, supplier reliability, complaints and meeting the standard requirements. Each of these criteria is broken down into sub-criteria, i.e. levels, and each level is evaluated by the correspondent number of points. The company defines various evaluation criteria for:

- the suppliers of raw material and services that directly affect the product quality;
- the suppliers of hazardous material and other services (consulting, legal work, safety and health at work, laboratory tests, etc.);
- the suppliers of consumables.
- At the end of the financial year, the Procurement – Sales Officer reviews individual deliveries according to suppliers and type of goods/services.

Every supplier is awarded the appropriate number of points, according to all 5 evaluation criteria. The average annual rating for each supplier is obtained by adding up the number of points according to the defined criteria. The Procurement – Sales Officer defines the supplier status based on the determined criteria that can be (Picture 2):

- A – approved supplier (> 70 points)
- B – temporarily approved supplier (from 50 to 70 points)
- C – unreliable supplier (below 50 points)

Evaluation is conducted by:			Evaluation criteria:			Date of evaluation:			Approval changes:			
Serial number	Supplier code:	Supplier	Quality	Delivery time	Price	Evaluation	Category	Range	Category	Range	Approved	Date
1						0	A	Approved				
2						0	B	Temporarily approved				
3						0	C	Unreliable				
4						0						
5						0						
6						0						
7						0						
8						0						
9						0						
10						0						
11						0						
12						0						
13						0						
14						0						
15						0						
16						0						
17						0						
18						0						
19						0						

Figure 2. Supplier-Provider Rating Scheme

The team formed to find a solution to the circumstances that affected the company had to make a decision on which raw rubber supplier on the domestic market may provide the raw material of approximately the same quality as the one the company had imported until the moment when the level of raw rubber stocks fell below the permitted level. The team concluded that the method they had been using to evaluate the suppliers was not sufficient and, as a solution to the problem, they defined the *checklist* (Table 1) with the criteria and sub-criteria for the

selection of the domestic market suppliers. Then they also added the new procedure *Defining procurement conditions and requirements* to the Quality Regulations.

Depending on the type of a product, service, raw material that is ordered as a new or a standard product, as well as on whether they are verified or unverified suppliers, in order to make the best decision, the Procurement Officer checks the supplier through the checklist presented below (table 1).

Table 1. Supplier checklist

Criteria	Description of criteria	Check
1. Basic data about supplier company	Basic information about the supplier company through the chosen portal( <a href="http://www.infopoint.rs/usluga-checkpoint">http://www.infopoint.rs/usluga-checkpoint</a> which monitors operations of buyers and suppliers in the country, provides insight into their credit rating and business rating and information on blockages accounts, court cases, etc.)	
2. Certificates	1. Certificate ISO 9001:2015 2. Other certificates (ISO 14001:2015, OHSAS 18001:2015, etc.)	
3. Material quality	1. Possession of a certificate on the origin and quality of the material	
	2. Compliance with a query	
	3. Delivery of samples for control and testing quality	

4. Fulfillment of obligations defined through contract	In order to ensure the fulfillment of the contract obligations, from our suppliers or customers we may require several instruments:	
	1. Authorized Promissory note*	
	2. Bank guarantee*	
	3. Other	
5. Price	Price quality ratio	
	Lowest price/quality on request	
	Market price/quality on request	
	High price/quality offered on request	
6. Fulfillment of company's requirements	1. Type and quantity	
	2. Applicable specifications, drawings, process requirements and other important technical characteristics	
	3. Statement on the purpose of the goods and other necessary data	
	4. Flexibility and delivery deadlines	
	5. Method of packaging and labeling	
	6. Method and place of delivery	
	7. Method of payment	
	8. Offer validity period	
7. Communication	1. Good service	
	2. Poor service	
8. References of the supplier	1. Business cooperation, clients	
Note:		

In order to maintain the quality level of its products, the company had the choose among three domestic raw rubber suppliers by means of the defined checklist and the conditions determined by the new procedure, as an additional method and with the aim of satisfying the raw material quality requirements, as well as the product quality, so as to satisfy the needs of very demanding customers.

### 3.2. Comparative Analysis of Exporting the Same Product by a Manufacturer in Automotive Industry Before and During the Global Crisis

The case study relates to a micro-enterprise in the automotive industry field, or more precisely to a manufacturer of special purpose trailers and semi-trailers. The company is a micro-enterprise with up to 10 employees and an annual turnover lower than 2 million euros. It manufactures two types of special units intended for on-road

and off-road driving. The company carries out the production operations outside the EU zone not taking the advantage of the possibilities, i.e. benefits of an exporting company (VAT refund), nor the opportunities of working in a duty-free zone (the opportunity of temporary import and refinement).

The observed period relates to the period from 2020 to 2022. Within that period, there was even a total interruption of the company operations in a certain number of months, followed by the reduced scope of business operations. For research purposes, the comparison of the reference unit export in 2022 and the export carried out in 2018 has been demonstrated. The comparison significance lies in the following:

- It is the same product type/variation/version;
- In both cases the destination EU country was the same, with the same central place of unloading;

- In both cases the buyer, i.e. end user was the same.
- In both cases the services of the same transport company were used for the transportation to the country/destination.

The importance of the study lies in the fact that the homologation requirements (ECE regulations) do not allow the replacement of one component with another unless it has priorly been defined in homologation documentation (the so-called alternative components). Or in other words, only the goods that have been pre-defined or approved can be purchased or acquired. Otherwise, additional tests, which require both time and costs, need to be carried out.

The company defined the following four categories: chassis, superstructure (extension), light and signalization and functional equipment. The following elements were defined as the critical purchase elements: brake axle, traction control device, wheels, led light signalization.

However, the observed comparison has certain limitations:

- In the supply chain, only the road transportation was observed as the only form of transportation the company carries out within EU;
- The critical elements like the brake axle was on stock and for the comparison purposes the first offer by the supplier was included;
- For the comparison financial aspect purposes, the cut-off was made after the critical elements had been received and customs-cleared (control device, wheels) and it did not include the subsequent leveling of element or service prices by a manufacturer or a supplier.

The company could not avoid the supply chain disruptions as the consequence of the global crises caused by COVID 19 and the military conflict in Ukraine. The observed

product unit that was taken as a reference due to the relativity of the comparison with the period prior to 2020 contains 32% of the components that were obtained from abroad either by direct import or by import through other suppliers. For the purpose of exporting to the EU countries, all components were obtained from 8 EU countries. The comparison of the two above-mentioned export cases emphasizes the following facts:

- At the moment when the cut-off was made, the total increase in the product element purchase prices was 36% as compared to the prices before the global crises, i.e. before February 2020;
- The global crisis caused the crucial element delivery time upon purchase to be extended by 4 weeks on average. In the case of the control device, the manufacturer was not able to define the delivery date;
- The unavailability of the elements at the manufacturer caused the creation of alternative supply channels, focusing on sales agents or more precisely dealers. However, the total transport of product elements and key elements from EU did not increase by more than 10%, counting the price per km or square meter;
- When the purchase was made on the domestic market, the deferred payment terms were either canceled or reduced due to the new circumstances;
- Given the good workshop positioning in terms of transport conditions and the allocation of human and material resource, the workshop level of equipment in the domain of tools and micro-climatic conditions, as well as the proximity of the service providers, there were no significant increases in labor and

service costs, nor the disruption in the production and service realization;

- The increase in the fuel prices caused by the leveling of prices at a global level led to the increase in operating costs;
- There was an increase in the bulk transport price (including the transport insurance) by 212%.

#### 4. Conclusion

The global crisis caused by COVID 19 and the war in Ukraine has transformed the whole world. All over the world, companies faced huge business losses. The change in market conditions caused by the global crisis forced many companies to transform their operations. Production companies encounter a number of challenges due to supply chain disruption on a global level, therefore many companies had to modify their operations on the domestic market and seek suppliers in their own countries. This paper and the conducted case studies aim at answering the question of how domestic manufacturing companies have responded to the current global crisis and the disruptions in supply chains they came across.

The significance of the first case study lies in the discovery that companies similar to the analyzed one need to have alternative solutions regarding the raw material procurement, and they should not be limited only to their global suppliers, but should instead foster the cooperation with the local market suppliers as well, thus avoiding the challenges arising from unpredictable circumstances, the import suspension caused by the global pandemic being one of them.

The second study leads us to the conclusion that following business strategy changes need to be carried out: to replace “delivered at place” (DAP) by “ex-works” strategy so that the production could meet the given deadlines, to reorganize the assembly process in accordance with new conditions, i.e. new procurement period, to reduce the number of elements within functional equipment with the aim to harmonize new retail price with the market demands, to improve the superstructure modularity in order to increase the sales offer, to carry out the additional selection of alternative components, principally in the critical element domain, with the goal to absorb the potential negative trends and changes in supply chains.

The analyzed studies make us conclude that the companies succeeded in adjusting their supply chains to the modified operation conditions caused by the global crisis. There were no significant differences among companies in terms of the supply chain disruptions, and the experience forced them to redesign their supply chains, which even resulted in the modifications regarding the supplier selection processes, procurement and production processes, and company strategies.

Based on the experience of the analyzed companies, the research findings may be practically used and implemented by managers, procurement and logistics officers to identify and develop efficient supply chain management measures during unpredictable circumstances. Further studies may aim at identifying efficient solutions for supply chain risk management.

## MODELLING FRAMEWORK FOR CRITICAL SUCCESS FACTORS OF GREEN SUPPLY CHAIN MANAGEMENT-AN INTEGRATED APPROACH OF PARETO, ISM AND SEM

**Abstract:** *The study aimed in identifying Green supply chain critical success factors, develop and validate the framework through integrated approach of ISM, MICMAC and SEM so as to promote green practices throughout the supply chain activities in Indian manufacturing sectors. Interpretive structural modelling(ISM) is applied to develop hierarchical contextual relationship among identified critical success factors via Pareto analysis. The methodology then follows classification of success factors into four clusters by Matrice d' Impacts Croisés-Multiplication Appliquée à un Classement (MICMAC) and statistical validation of the ISM model through Structural Equation Modelling(SEM) by AMOS. In this study, 16 critical success factors of Green supply chain practices for manufacturing industries were identified, followed by development of an ISM model using 16 critical success factors, later the model was statistically verified that identified nine CSF's responsible for generating SEM model by satisfying all the model fit indices. The linkage variables identified are Green manufacturing, Green Procurement, Green marketing and Distribution, Green purchasing, Supplier cooperation, Customer cooperation, Environmental strategies and management, Environmental Participation and Green training that are forming the driving force for practising green supply chain. Research limitations/implications: The results of the study are restricted to manufacturing industries, which might vary when applied for other sectors. The developed model on green supply chain management practices would help policy makers, decision makers, researchers and industry professionals to anticipate potential success factors to implement green supply chain practices. Accordingly, the focus on critical success factors would be prioritized for obtaining better performance of supply chain and greening the chain.*

**Keywords:** *Green Supply chain, factors, Pareto analysis, SSIM, Transitivity matrix, Digraph, ISM Framework, MICMAC analysis.*

### 1. Introduction

Modern manufacturing industries are striving hard to develop a supply chain process which can minimize the negative impact on environment. Industrial impact on the environment is not only confined to greenhouse gas emissions but also leads to

water shortages, difficulties in usage of the land, hazardous waste, water contamination, deforestation, pollution levels, and energy use are all essential issues that are important to bring it in the light. (Maertens et al 2012, Memia 2018, De Carvalho et al 2020, Vijayvargy et al 2017). The noteworthy truth is that the leading 2500 global corporations contribute to more than 20% of global

greenhouse gas emissions, and their supplier networks constitute a significant share of emission levels arising from business operations. As a result of globalization, distribution systems for goods and services have become extremely complicated, (Reuter et al., 2010). Therefore, in order to manage the supply chain and minimize its negative impact on environment the theory of Green Supply Chain Management(GSCM) was created which also address these ecological consequences.

Through the exhaustive literature survey, 28 GSCM factors are identified including both external and internal factors influencing Green practices in manufacturing supply chain. Identification and quantification of these factors is more challenging and important also for the sustainable development of the organization. Therefore, our Research is an effort to find the most relevant factors of GSCM and it is called as Critical Success Factors.

Pareto chart was constructed to identify the critical success factors. Therefore, by using the 80-20 rule, we narrowed down the 28 GSCM factors to 16 critical success factors. The success factors are analysed using Interpretive structural modelling(ISM) and then a proposed model is built considering MICMAC that specifies the association

among them. ISM methodology typically develops a compact model based on the results from Delphi technique. The Delphi panel consisted the experts from Industry as well as Academia. The Expert opinion from Industry as well as academia together is considered to build an ISM model that indicates the position and importance of success factors along with the alternatives that converts the fuzzy information into responsive model based on discussions during Delphi technique. Further Structural Equation modelling (SEM) was applied for the theoretical ISM model to statistically validate the results. The current study aimed in developing a hybrid model that combines ISM and SEM. The distinctive feature of the study is that offers a combined approach for ISM-SEM for analysing the factors influencing Green Supply chain practices in Indian manufacturing industries. In the present study, structural relationship SEM approach has been used to validate the ISM based model.

## 2. Literature Review

The Literature has been reviewed from the perspectives of Green supply chain factors, ISM and SEM applications as presented in Tables 1-3.

**Table 1.** Review on Green Supply Chain Manufacturing

<b>Author and Year</b>	<b>Objectives</b>	<b>Methodology</b>	<b>outcomes</b>
Lin et al.,(2011)	To identify the elements that influence the performance of automobile industries through Fuzzy DEMATEL approach.	Fuzzy DEMATEL approach.	Findings show that use of eco material is the significant factor.
Bhool et al.,(2013)	To identify enablers and barriers of GSCM in different sectors of manufacturing industries.	Questionnaire based survey and mean, SD of GSCM drivers through SPSS.	Government rules & legislation' have more important and crucial for adoption of GSCM for 4-wheeler industries
Zhu et al.,(2007)	To determine GSCM practices and implementation strategies to obtain the associated link and measure the efficiency of the obtained relationship.	Statistical analysis by ANOVA Test.	Electrical and electronic industry practise Green supply chain more effectively than other industries in China.

Surajit et al.,(2014)	To build a GSCM framework for the rubber industry.	ISM and MICMAC approach	A tenfold framework was developed that might assist rubber manufacturing industries.
Panpatil et al.,(2022)	To obtain the association between GSCM practices and measure its impact on performance of Industry.	Fuzzy MICMAC.	Developed an integrated model that reveals direct and incidental effect on GSCM practices. The results also showed that driver GSCP's have deliberate importance and dependant GSCP's are more performance oriented.
Venkatesa Narayanan et al.,(2021)	To know the relationship between elements of learning organization and green supply chain practices in manufacturing sector.	Multiple Linear Regression, ISM and MICMAC approach.	Findings of the study identified Green distribution and reverse logistics as driving factors.
Diabat et al.,(2011)	To develop and validate a GSCM model for a manufacturing company.	ISM, MICMAC approach.	The developed model results in increasing the overall cost of the product.
Waqas et al.,(2020)	To determine the association between RL barriers in manufacturing industries, Pakistan.	ISM and MICMAC approach	The model developed identified the obstacles and will help policymakers to frame strategies focusing on major obstacles identified through ISM, MICMAC.
Paul et al.,(2022)	To examine critical Success factors for sustainability in Bangladesh wood industries.	Principal Component Analysis(PCA), ISM and MICMAC Approach.	The findings reveal that research and development, supplier relations, and using eco-friendly technology are the most significant CSFs of the Bangladeshi wood industry.

**Table 2.** Literature study on SEM applications

Author and Year	Objectives	Methodology	outcomes	Sector applied
Thirupathi et al(2016)	To develop hybrid model using ISM and SEM techniques.	ISM and SEM	Findings of the study show that strong relationship exists between sustainable manufacturing enablers.	Automotive component manufacturing organisation
Masoumik et al(2015)	To develop a conceptual model on GSCM initiatives.	ANP , SEM	A conceptual framework on Green supply chain imitativeness is developed.	Business Sector
Khaksar et al(2016)	To determine the relationship between GSCM Factors.	Correlation and SEM	There is a positive and significant relationship between GSCM factors and organizational performance.	Cement Industry
Agarwal et al(2021)	To find out the different barriers of GSCM practices	SEM	A contextual relationship among the identified barriers is developed and model is statistically validated using SEM approach.	Rubber Industry.
Umar et al(2021)	To determine the influence of industry performance in terms of technology, environment through GSCM practices acting as mediating element.	SEM	The outcomes indicate that green supply chain practices mediate the economic and environment performance.	Manufacturing firms.

Juma et al(2022)	To identify the barriers that hinder from implementing GSCM practices.	SEM	SEM identified and statistically validated the factors of GSCM practices that influence green organizational performance.	Jordan manufacturing firms
Amjad et al(2022)	To investigate the influential effect of GSCM practices in leather industry considering competitiveness and investment recovery as mediating factors.	PLS SEM	Findings of the study reveal that GSCM practices effect organizational performance.	Leather Industries.
Nureen et al(2022)	The study attempts to develop a conceptual model between GSCM practices as mediating factors and institutional pressure as moderating factor on organizational performance.	PLS SEM	Findings of the analysis show that technical practices and performance are moderated by institutional pressure.	Manufacturing industries.

**Table 3.** Review on ISM applications

Author and Year	Objectives	Methodology	outcomes	Sector applied
Mandal et al(1994)	To develop an ISM model that shows the interrelationship between different criteria level in vendor selection.	Dickson’s study identified vendor selection criteria. Out of 23 identified criteria’s 11 have been finalised as most important.	Developed vendor selection process framework based on qualitative and quantitative approach.	Vendor selection for Purchasing department in Indian Engineering Industries.
Raut et al(2017)	To investigate CSF for cloud computing adoption in Indian SME’s.	Interpretive structural modelling and Multi criteria decision making model MICMAC analysis.	Previous technological experience is identified as most influential critical success factor for harnessing the benefits of Cloud computing.	Indian micro, small and medium enterprises.
Beikkhakhian et al(2015)	To evaluate agile supplier selection criteria and rank the suppliers.	Interpretive structural modelling, Fuzzy AHP, Fuzzy TOPSIS.	Supply chain agility model is developed by ISM procedure that identified delivery speed as highest driving variable.	Manufacturing industries.
Ali et al(2020)	To build a model by identifying barriers to lean supply chain.	ISM to identify the contextual relationship and MICMAC analysis to determine Supply chain barriers.	Developed model that shows the contextual relationship between the barriers.	Apparel manufacturing Industries.
Talib et al(2011)	To develop a hierarchy of TQM barriers that identifies the relationship between the identified barriers.	ISM approach to know the mutual dependency of one barrier over the other. MICMAC to cluster the barriers and know their dependency.	Developed ISM based TQM barriers model and determined driver, dependent cluster of TQM barriers	Service sectors.
Khan et al(2015)	To model the interrelationships among retail brand experience variables.	ISM to develop the framework and MICMAC approach to cluster the variables.	Findings of the study revealed that retail brand experience is influenced by variables with high driving power and weak driving power.	Retail sectors.

Attri et al(2017)	To develop a 5S hierarchy based model and identify the dependency of one barrier over the other.	ISM to identify the relationship among identified barriers and MICMAC to know dependant and independent barriers	Developed a hierarchy based model.	Indian manufacturing industries.
Shibin et al(2017)	To develop a Flexible Green supply chain model both barrier and enabler based.	Total interpretive structural modelling(TISM) to identify the relationship between barriers and enablers.	Developed Barrier, enabler framework for Flexible Green supply chain	Manufacturing organizations.
Thakur et al(2016)	To identify and analyse the interrelationships among medical waste disposal care barriers	ISM and Fuzzy MICMAC to prioritize barriers of health care waste management system.	Hierarchical ISM framework developed identifies the interrelationship between the identified barriers.	Health care sector
Nandal et al(2019)	To examine solar power implementation in thermal plants by establishing hierarchical framework that determines the interrelationship between solar power barriers.	ISM to determine the circumstantial relationships among key barriers and MICMAC approach to validate the ISM model.	Developed contextual framework that is validated through MICMAC and identified the most influential barriers that are hindering the installation of solar power in thermal power plants.	Indian thermal power plants.

From the literature review several factors are identified that require considerable amount of time and energy for managers to get adapted to Green supply chain practices. With the development of concise set of GSCM factors, which may provide quicker and easier support to take initiation for practising GSCM in manufacturing industries. The major problem with the available GSCM models is that the factors themselves need an understanding of being applied in the defined sector and also the measurement of the model through statistical techniques. Therefore, this gap led to the formation of three main objectives:

- 1) To identify the key Green supply chain factors of the Indian manufacturing industries from the literature and expert opinion.
- 2) To develop an appropriate hierarchy and contextual relationship of identified factors using interpretive structural modelling (ISM) and to classify these factors using Matrice d' Impacts Croisés-Multiplication Appliquée á un Classement (MICMAC)

- 3) To validate the ISM model using structural equation modeling (SEM).

The subsequent tables 1,2 and 3 present literatures with respect to Green supply chain in Manufacturing industries, SEM applications and ISM applications.

Based on the literature review on ISM, it is understood that there exists scope for selecting appropriate number of facilitators to simplify the situation. Literature also identifies that SEM being implemented independently fails to build a model on logical interpretation. Also applying only ISM model fails to provide the statistical results. Therefore, the integration of ISM and SEM technique builds a model that proves the logical interpretation from experts by subjecting it to statistical validation.

ISM model developed based on expert opinion will identify factors which can be further statistically verified. This has been expressed by various authors in their study Balon (2016), Chin (2015), Deng et al (2019), Mahmoudi et al(2016). Now the challenge lies in validation of theoretical

model developed from ISM due to the limitation, of strong theory to interpret the developed model. The integration of ISM and SEM offers a complete solution to the above problem. In the current study authors have made an attempt to develop one such model that is statistically valid.

### 3. Methodology

A trianalysis method was carried out in this study analysing both quantitative, qualitative data obtained from study. The measureable analysis was based on Questionnaire survey, while qualitative was on Delphi technique on having semi structured interview with panel consisting of members from Industry and academicians. The study consisted of trifold analysis ISM, MICMAC and SEM within Indian manufacturing industries. Although ISM is a competent method to model the facilitators but it increases the complexity of the system by raising the number of facilitators. Therefore, the facilitators modelled from ISM and Micmac needs a statistical validation. In order to overcome this problem SEM and ISM are combined to validate the relationship between success factors. The MICMAC analysis helps to cluster the factors in four quadrants and group them accordingly based on driving and dependence power.

The critical success factors(CSF) are identified from literature review and expert opinion survey. A thorough literature review has been carried out referring research articles for the period 2008 to 2022 from Scopus, Emerald, Taylor and Francis database. This was followed by summarizing expert's opinion from academics and industry. Based on the opinion from academicians and industry experts 28 factors were identified. In order to reduce the factor intricacy and develop a framework further Interpretive structural modelling to conceptually validate the model and Structural Equation modelling(SEM) has

been used to statistically validate the ISM model.

#### **Frequently used GSCM factors from Literature study**

Firms have many objectives such as better image of brand, to get competitive advantage, better utilization of sources, increased profits, etc. In the process of achieving these objectives firms apply various strategies, one such strategy would be to implement GSCM practices. GSCM might be a more effective means to balance ecological, financial and societal performances. (Diabat, Govindan, 2011). Supply chain management has significant impacts on the environment which includes-release of pollutants and emissions, health hazards affecting the workers, wastage of materials, etc. Hence firms are trying to reduce the negative environmental impact by including environmentally friendly strategies into the supply chain. (Sarkis, 2012) Therefore the work carried out focuses on bringing out the most important environmental concerns and strategies pertaining to them and to generate a generalized framework that may be applicable to industries. Therefore, from the literature frequently used factors of GSCM by various authors are identified and listed in table 4.

From the literature the identified 28 GSCM factors are as depicted in table 4, Further these 28 factors are subjected to Pareto analysis to identify vital few that are critical ones and responsible for implementation for green practices in manufacturing industries.

**Table 4.** GSCM factors used by the various researchers

Sl No	Components	Researchers	Frequency
1	Green Purchasing	Famiyeh (2017), Feng (2017), Khan (2017), Khan (2017), Laari (2015), Sharma (2016), Vijayvargy et al., (2017), Younis (2016), Liu (2018), Agi (2017), Ahmad et al., (2021), Abdel-Baset et al., (2019), Çankaya et al., (2018), Cousins et al., (2019), Badi et al., (2019), Sellitto et al., (2019), Seman et al., (2019), Sahar et al., (2020), Ilyas et al., (2020), Novitasari et al., (2021), Younis et al., (2019), Zhu (2010), Thipparat (2011), Choudhary (2011), Azevedo (2012), Babu (2012), Laosirihongthong et al., (2013), Jabbour et al., (2015), Jabbour (2014), Chin et al., (2015), Lee et al., (2013), Hasan (2013)	32

## 4. Pareto chart

A Pareto analysis helps to prioritize decisions and identify the major critical factors that might be responsible for firm's performance. Brooks et al (2014). It is also defined as 80/20 rule as it explains about 80% of the firm's benefit is from 20% of the factors. With this approach among the frequently identified

factors of Green supply chain only vital few that is 20% of the critical factors are responsible for 80% of the firm's success are identified through Pareto analysis. A Pareto chart is constructed as shown in Figure 1 that highlights 20% of the green supply chain factors constituting about 16 factors responsible for 80% of the firm's outcome.

Figure 1. Pareto chart for GSCM Factors

Based on the literature review, we identified nearly 28 GSCM factors in our study. Pareto chart to find out the critical success factors. On the Pareto diagram as shown in figure 1, 28 factors are listed on the x-axis in the order of their contribution to the overall influences in descending order. Hence, using the 80-20 rule, we narrowed down the 28 GSCM factors to 16 critical success factors.

### Interpretive Structural Modelling

Structural Self-Interactive Matrix

The SSIM matrix was developed by plotting the relationship between two facilitators i.e., i and j. The relations were coded with V, A, X and O. SSIM matrix is depicted in table 6.

V is represented when GSCMF i will assist GSCMF j.

A is represented when GSCMF j will assist GSCMF i.

X is represented when GSCMF i and j assist each other.

O is represented when both GSCMF i and j are not related to each other.

An example of the application of GSCMF- GSCMF 6 assists GSCMF 16 and hence it is coded as V.

GSCMF 14 assists GSCMF 7 and hence it is coded as A.

GSCMF 5 and GSCMF 15 assist each other and hence, they are coded as X.

GSCMF 6 and GSCMF 8 are not related to each other and hence they are coded as O.

the relationships between two facilitators are binary coded for codes V, A, X and O respectively, the coding procedure is as shown in table 5. Table 7 represents Initial reachability matrix that follows the binary coding for SSIM.

**Table 5. Binary coded table**

**Level partitions**

The reachability set and antecedent set for each GSCMF are determined using the final reachability matrix. The reachability set includes GSCMFs and other GSCMFs that may aid in their attainment, while the antecedent set comprises GSCMFs and other GSCMFs that aid in their attainment. The intersection of these sets is then calculated for each GSCMF. The top-level GSCMFs in the ISM hierarchy are those with the same reachability and intersection sets. The

hierarchy's top-level GSCMFs would not assist in the achievement of any GSCMFs beyond their own level. It is isolated from the other GSCMFs once the top-level GSCMFs have been discovered (Step 4: Partitioning of reachability matrix). The method is then restarted to determine the GSCMF in the next level. This procedure is repeated until the level of each GSCMF is determined (Step 4: Partitioning of reachability matrix). These stages contribute to the construction of the diagram and the final Framework.

**Table 9.** Level Partitioning Matrix

### 5. Building the ISM model

The structural model is created using the final reachability matrix (Step 3: Transitivity matrix). An arrow pointing from i to j indicates, there is a relationship between the GSCMFs i and j. A directed graph, or digraph, is what this graph is called. The digraph (Figure 2) is turned into the ISM-based framework when the transitivity is removed (Figure 3). I

**Figure 2.** Digraph

#### ISM based Framework

A digraph (figure 2) is used to illustrate the factors and their relationships in the form of nodal representation. (Mahmoudi et al., 2013).

15. Financial implications
16. Reverse logistics

From the reachability matrix, a digraph was constructed that represents the facilitators and their interdependence with each other. In the digraph that obtained, Green Supply Chain critical success factors have been classified into 10 levels according to the level partitioning matrix. According to the diagram, the highest success factor is positioned at the top of the digraph and the second-level facilitator is placed at the second position and so on until the bottom level is placed at the lowest position in the digraph. Here, GSCMF 6 lies in the topmost level- Level 1 while GSCMF 13 in the bottom most level, the 10<sup>th</sup> level.

### Interpretive structural modelling Framework

The digraph is transformed into an ISM model by replacing the nodes of the facilitators with their respective names. From this framework, it can be seen that the facilitators are arranged according to their levels. Customer cooperation lies in level one being the most highly independent facilitator whereas green policies lie in the 10th level being the most highly dependent facilitator.

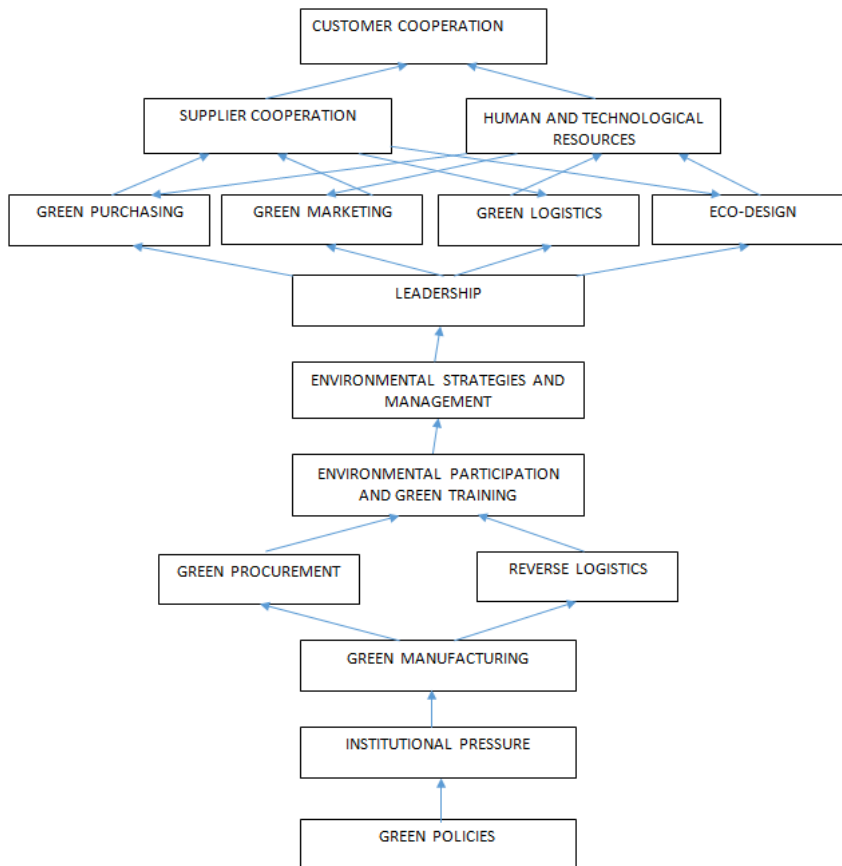

Figure 3. ISM based Framework

**6. MICMAC Analysis**

Matrice d'impacts croisés multiplication appliquée á un classment (Cross impact matrix-multiplication applied to classification), was developed by Duperrin and Godet (1973) at the CEA between 1972 and 1974 (Sexana et al,1990) to investigate the distribution of associates through response paths and loops for developing hierarchies for members of an element set (Purohit,2017) and is a structural prospective analysis used to investigate indirect relationships (Sexana et al,1990). MICMAC analysis can be used to identify and investigate the elements in a sophisticated and complex system with the goal of separating the variables' driving and dependency powers (Faisal et al. 2007). Variable X affects Y, variable Y affects Z, X and Z have no direct influence on Y, but their association with Y is a cross-correlation, where any modification in X impacts Z. Gray area exploration is another

name for this type of analysis (Dubey et al,2014).

This analysis enhances the ISM technique by examining limitations that are commonly associated with the ISM method: it examines the connection "yes" or "no" and ignores the "gray area" between 0 and 1. (Sushil et al,2012). The construction of a graph that classifies components based on driving and dependence power is a part of the MICMAC analysis. To get at the study's findings and conclusions, MICMAC analysis is utilized to characterize the components and validate the interpretive structural model factors. (Ahmad et al,2019).

According to Figure 3.4, the Micmac analysis shows that most of the facilitators have high driving and dependence power, they were found to be linkage variables, they work as a catalyst to the dependant variables while they are relative to independent variables.

**Figure 4. MICMAC Graph**

Facilitator 2, 7, 3, 1, 10, 6, 9, 14, i.e., Green Manufacturing, Green Procurement, Green Marketing and Distribution, Green Purchasing, Supplier Cooperation, Customer Cooperation, Environmental Strategies and Management, Environmental Participation and Green Training respectively were found to be the linkage variables through the analysis. Facilitator 8 and 13, i.e., Institutional Pressures and Green Policies respectively, has a higher driving power than the depending power. The dependent variables are related to the independent variables and this is possible because of linkage variables.

## 7. Model analysis using Structural Equation Modelling (SEM)

Structural Equation Modelling is a combined technique applying regression and factor analysis to validate survey based results statistically. (Referencing).

Exploratory factor analysis(EFA) is applied on sample size of 511 units (n=511) for the 16 barriers of green supply chain to extract

the factors that are Principal factors using SPSS. In the study Principal component analysis with varimax rotation was used to group the items under common factor by following the principle of Eigen value criterion. The Eigen values with greater than one are considered A total of six factors with eigen value greater than 1 are considered as shown in Table 11. The factors are grouped into six sections namely Green manufacturing, Green logistics, Customer cooperation, Environmental strategies and management, Supplier cooperation, Reverse logistics all of which have an Eigen value of greater than 1 and factor loading of greater than 0.5 with more than three items for each factor. Cronbach's alpha was used to measure the internal consistency of the instrument.

Kaiser Mayer Olkin(KMO) test was conducted to check the adequacy of the collected data. The table 10 presents the statistics of KMO result showing that the data are adequate. Data with KMO values greater than 0.6 are considered adequate. Factor analysis

**Table 10.** KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.811
Bartlett's Test of Sphericity	Approx. Chi-Square	4191.255
	df	253
	Sig.	.000

The outline of Principal Component Analysis is depicted in table 11 that explains the total variance accumulated by six components is 71.9%. Based on EFA, subsequent six Principal components were selected based on Eigen values greater than 1. Further in order to assess the significance of the data through the items, the commonalities derived from the factor analysis were reviewed. The item loading greater than 0.5 were considered (Fornell et al,1981)). For the final instrument 23 items

were extracted based on those variables having a loading of atleast 0.5 on single factor. Table 11 summarized the extraction of six components through factor analysis.

### Model Fit Summary

The values of the model fit are fully satisfactory as per social science research. All the fit indices are within the acceptable range as shown in table 13. (Hair et al 2009).

## 8. Results and Discussion

The study has identified 28 key Green Supply Chain Management Facilitators by reviewing a number of research articles, which were run through Pareto analysis that resulted in the identification of 16 predominant factors.

It is moreover evident that no single GSCM factor would be self-determining for green supply chain implementation in an organization, therefore, it becomes more important to identify the relationship of GSCM factor with each other. ISM methodology is used to develop relationship among various factors for each dimension of GSCM implementation. The practitioners need to concentrate on these factors more cautiously during GSCM implementation in their organizations. On the other hand, academicians may be encouraged to categorize different other issues, which are important in addressing these GSCMF.

ISM model identifies the hierarchy of actions to be taken by practitioners in order to maximize the effect of these GSCMF in order to implement GSCM successfully. Based on the level partitioning matrix, it was found that framework is divided into ten levels where facilitator 13 (Level 10) which is Green Policies was the most dependent while facilitator 6 (Level 1) Customer Cooperation is the most independent.

Micmac Analysis identified 8 facilitators to be linkage variables and 2 facilitators to be dependent variables. The linkage variables were Green Manufacturing, Green Procurement, Green Marketing and Distribution, Green Purchasing, Supplier Cooperation, Customer Cooperation, Environmental Strategies and Management, Environmental Participation and Green Training and Dependent variables were found to be Institutional Pressures and Green Policies. The factors were statistically verified using structural equation modelling

and the model fit satisfied all the fit indices thereby proving the factors to be critically responsible for implementation of Green supply chain.

The ISM model was further validated statistically through Structural equation modelling, where EFA resulted in six components whose Eigen values are greater than 1, The six success factors resulted from EFA are GM, GL, CC, ESM, SC, RL. A final six component model was developed through statistical validation.

## 9. Conclusion

Manufacturing industries are finding it difficult to focus on green supply chain practices due to its multifarious environment. The authors in the study developed a model to address the issue of practising green supply chain activities. The model is built considering the opinion from experts and through literature study, this helped in identification of frequently used success factors which were further confirmed from respective subject experts from industries. Then Interpretive structural modelling was applied to know the relationship between the success factors. 28 success factors identified from literature study were narrowed down to 16 through ISM MICMAC approach. The 16 factor ISM model was statistically validated through structural equation modelling that resulted in critical success factors. The model exhibiting the inter relationship may be used by policy and decision makers to implement green supply chain practices in manufacturing industries. The model developed in limited to its use only to manufacturing sectors in Indian scenario, the results may vary if the model is applied to other sectors. Future studies can be carried out in other sectors to implement green practices in their supply chain.

## EXPECTATIONS TOWARDS SUPPLIERS IN TERMS OF ENSURING AND IMPROVING THE QUALITY OF PRODUCTS AND PROCESSES

**Abstract:** *The aim of the article is to present current trends in the expectations of producers operating on the B2B market towards suppliers in the field of ensuring and improving the quality of products and processes. The analysis of the literature allows to conclude that the fulfillment of these expectations by suppliers is largely achieved through the implementation of guidelines contained in international organizational standards in the field of quality and environmental management, as well as elements of the Toyota Production System (such as Kaizen, 5S, TPM) or the based on the concept of Lean Management. The results of the empirical research (with the use of the CATI technique) indicate that manufacturing companies that are buyers in their expectations towards suppliers focus mainly on improving the technical quality of products, shortening the time of order fulfillment, reducing operating costs.*

**Keywords:** *Quality, Cooperation, Suppliers, ISO*

### 1. Introduction

Most often, the expectations of customers on the B2B market (especially from industrial sectors, and in particular OEMs - Original Equipment Manufacturers towards suppliers focus on ensuring product quality, guaranteeing timely deliveries and reducing costs (Ekici, 2013). Therefore, these companies impose individualized requirements on their suppliers through detailed specifications specifying not only issues related to quality assurance (guaranteeing the technical quality of products), but also organizational issues related to increasing the effectiveness of processes (e.g. shortening cycles of activities), efficiency (reducing costs), and also the requirements related to the need to reduce the burden on the environment (Forkmann et al., 2016). These requirements are increasingly important criteria for the initial and periodic assessment of suppliers (Taherdoos and Brard, 2016). This approach

is a significant incentive for suppliers to make efforts to improve their operations by introducing systemic quality and environmental management, as well as operational improvement tools, such as elements of the Toyota Production System or Lean Management projects. The topic of cooperation with suppliers is relatively widely discussed in the literature (He et al., 2022; Baghizadeh et al., 2021; Zimon and Madzik, 2020), but it is still important and up-to-date due to the changing trends and threats resulting from the current ongoing crises (Deligiannis et al., 2023). As Allenbacher and Berg (2023) rightly point out, it is now crucial for manufacturing companies to implement the adopted strategies beyond the firm level. Manufacturing companies therefore use different concepts and methods to get suppliers to follow the broader strategy outlined in the supply chain (Zhang et al., 2020). This is an important issue as many studies suggest that direct suppliers can be a

---

Email: [dzimon@wsiz.edu.pl](mailto:dzimon@wsiz.edu.pl)

catalyst for the diffusion of requirements to sub-suppliers further upstream in the supply chain (Allenbacher and Berg, 2023; Grimm et al., 2016). Therefore, it seems particularly important for manufacturing companies to formulate clear guidelines on quality, environmental or operational issues that should be followed by suppliers. This will not only affect the effectiveness of cooperation within the consignee-supplier, but may also improve the functioning of the entire supply chain (Li et al., 2017). As rightly emphasized by O'Connor et al. (2020), activities contributing to closer cooperation with suppliers within the supply chain increase its innovation, responsiveness and profitability. In view of the above considerations, the aim of the article is to identify the requirements of manufacturing companies towards suppliers. The obtained research results will allow for a better understanding of the expectations of manufacturing companies as part of relations with suppliers, which, as noted earlier, affects supply chain management strategies. (Lu, et al., 2022). In order to achieve this goal (based on a wide literature review), eight key requirements of manufacturing companies towards suppliers were identified. These are respectively:

- Improving the technical quality of products (Kang and Um, 2023),
- Shortening the time of order fulfillment (Harbi et al., 2018),
- Reducing operational costs by reducing the level of non-compliance and waste (Yoo et al., 2019),
- Reducing the risk of non-compliance in operational processes (Zimon and Madzík, 2020),
- Reducing the risk of hazards related to products (Wieteska, 2020; Li and Chen, 2019),
- Improving the environmental performance of products (Wang et al., 2021; Salem et al., 2023),

- Reducing the negative impact of processes on the environment (Bartos et al., 2022, Zimon et al., 2022),
- Improved standardization of activities (Zimon et al., 2020).

The research covered Polish large and medium-sized manufacturing companies operating on the B2B market. All the analyzed enterprises implemented the requirements of the ISO 9001 standard, more than half of them implemented the requirements of ISO 14001, some of the surveyed enterprises implemented concepts such as TPS or Lean Management. This is an important fact, because the research results available in the literature indicate that the use of management concepts and systems has a positive effect on building proper relationships with suppliers. (Dellana et al., 2020; Zimon et al., 2020; Rojo-Gallego-Burin et al., 2020).

## 2. Methodology of Research and Results

In order to determine the importance of expectations towards suppliers in terms of ensuring and improving the quality of products and processes, empirical study was carried out. These studies were performed using the Computer Assisted Telephone Interview (CATI) technique. The study covered 150 manufacturers operating on the B2B market (employing over 49 employees) from the automotive, electromechanical and chemical sectors. The study was commissioned to a specialized research agency, which made a targeted selection of companies registered in the Bisnode database. All companies participating in the study implemented a quality management system based on the requirements of the international management standard ISO 9001. The surveyed enterprises assigned the indicated

expectations towards suppliers in terms of ensuring and improving the quality of products and processes the appropriate ranks on a scale from 5 (the most important criterion) to 1 (the least important criterion).

Detailed study results are presented in the tables 1-4.

The conducted cross-sectional analyzes of the results of empirical research allow to indicate interesting observations.

**Table 1.** The importance of expectations towards suppliers in terms of ensuring and improving the quality of products and processes (general, comparison between enterprises due to the origin of capital; rank averages)

Expectations towards suppliers	General N=150	Origin of capital	
		Polish N=79	Foreign N=71
Improving the technical quality of products	4.77	4.74	4.82
Shortening the time of order fulfillment	4.71	4.75	4.66
Reducing operational costs by reducing the level of non-compliance and waste	4.65	4.63	4.67
Reducing the risk of non-compliance in operational processes	4.41	4.41	4.41
Reducing the risk of hazards related to products	4.39	4.37	4.41
Improving the environmental performance of products	4.37	4.34	4.42
Reducing the negative impact of processes on the environment	4.23	4.24	4.22
Improved standardization of activities	4.21	4.23	4.19

Improving the technical quality of products as an expectation towards suppliers is particularly important for large organizations with foreign capital, as well as for companies from the automotive and electromechanical sectors. In turn, shortening the time of order fulfillment is very important for large producers with Polish capital and companies from the automotive sector. Companies that have implemented the concepts of Toyota Production System and Lean Management clearly focus their expectations towards suppliers in terms of reducing operating costs by reducing the level of non-compliance and waste. The study results indicate that medium-sized organizations (employing 50-250 employees) and companies from the automotive sector attach greater importance to reducing the risk of non-compliance in operational processes. On the other hand, large producers (employing over 250 employees) and business organizations that have implemented the

Toyota Production System and Lean Management concepts focus on expectations towards suppliers in terms of reducing the risk of product-related hazards. Improving the environmental performance of products by suppliers is of particular importance in the case of large producers, as well as for companies from the chemical sector. It should also be noted that for medium-sized producers and for enterprises that have implemented an environmental management system as expectations towards partners who are the source of purchases, it is important to reduce the negative impact of processes on the environment as well as to improve the standardization of processes.

Analyzing the results of the research and the emerging trends in the scope of expectations towards suppliers, it should be assumed that they will increasingly focus on:

- ensuring the quality of products (reducing the risk of non-compliance and improving safety) and the possibilities of their

improvement (especially through closer cooperation in the field of joint research and development works),

- reducing the negative impact of products and processes on the environment (over 50% of the surveyed buyer entities have implemented an environmental management system, especially

representatives of the chemical and automotive sectors), and

- increasing the level of efficiency of processes by shortening their cycles (about 20% of the surveyed organizations have implemented elements of TPS and implement Lean Management projects, especially in the automotive sector).

**Table 2.** The importance of expectations towards suppliers in terms of ensuring and improving the quality of products and processes (comparison between enterprises by number of employees; average ranks)

Expectations towards suppliers	General N=150	Number of employees	
		50-250 N=65	Over 250 N=85
Improving the technical quality of products	4,77	4.71	4.83
Shortening the time of order fulfillment	4.71	4.65	4.76
Reducing operational costs by reducing the level of non-compliance and waste	4.65	4.65	4.64
Reducing the risk of non-compliance in operational processes	4.41	4.46	4.37
Reducing the risk of hazards related to products	4.39	4.28	4.46
Improving the environmental performance of products	4.37	4.25	4.47
Reducing the negative impact of processes on the environment	4.23	4.28	4.20
Improved standardization of activities	4.21	4.26	4.17

**Table 3.** The importance of expectations towards suppliers in terms of ensuring and improving the quality of products and processes (comparison between enterprises by sector; rank averages)

Expectations towards suppliers	General N=150	Sector		
		Automotive N=63	Electromechanical N=36	Chemical N=51
Improving the technical quality of products	4,77	4.83	4.81	4.68
Shortening the time of order fulfillment	4.71	4.85	4.55	4.65
Reducing operational costs by reducing the level of non-compliance and waste	4.65	4.73	4.55	4.62
Reducing the risk of non-compliance in operational processes	4.41	4.53	4.30	4.33
Reducing the risk of hazards related to products	4.39	4.47	4.39	4.26
Improving the environmental performance of products	4.37	4.34	4.36	4.42
Reducing the negative impact of processes on the environment	4.23	4.29	4.12	4.24
Improved standardization of activities	4.21	4.29	4.12	4.17

**Table 4.** The importance of expectations towards suppliers in terms of ensuring and improving the quality of products and processes (comparison between enterprises due to the implemented tools for improving products and processes; rank averages)

Expectations towards suppliers	General N=150	ISO 14001 N=76	TPS N=39	Lean Management N=24
Improving the technical quality of products	4.77	4.80	4.84	4.85
Shortening the time of order fulfillment	4.71	4.65	4.79	4.79
Reducing operational costs by reducing the level of non-compliance and waste	4.65	4.66	4.68	4.73
Reducing the risk of non-compliance in operational processes	4.41	4.35	4.45	4.32
Reducing the risk of hazards related to products	4.39	4.39	4.50	4.64
Improving the environmental performance of products	4.37	4.32	4.44	4.32
Reducing the negative impact of processes on the environment	4.23	4.50	4.30	4.36
Improved standardization of activities	4.21	4.25	4.36	4.32

### 3. Conclusion

The results of the conducted study indicate that the surveyed enterprises, as the most important expectations towards suppliers, focused on improving the technical quality of products, shortening the time of order fulfillment, reducing operating costs by reducing the level of non-compliance and waste. The study results also indicate that the expectations of the surveyed manufacturers towards suppliers in terms of reducing the risk of non-compliance in operational processes, reducing the risk of hazards related to products (possibility of technical non-compliance) as well as improving the environmental performance of products should also be considered significant.

Recapitulating the above considerations, it should be stated that the requirements imposed on suppliers by OEMs in the field of implementing systemic quality and environmental management, as well as improving the efficiency and effectiveness of processes brings significant benefits to supply chain participants

The effective implementation of the quality

management system undoubtedly contributes to ensuring the technical quality of products by supervising operational processes and reducing the level of risk of hazards.

In turn, the effective implementation of environmental management system contributes to reducing the negative impact on the environment by reducing the consumption of natural resources, emissions of harmful factors and waste. By effectively implementing system solutions in the field of quality and environmental management, as well as elements of TPS and Lean Management projects, suppliers can achieve significant benefits. These benefits include:

- a higher level of product quality assurance,
- increase in effectiveness (measured by the degree of achievement of the assumed objectives, improvement of efficiency) and efficiency of processes (by reducing the costs of activities by increasing the efficiency of employees / infrastructure, or eliminating unnecessary activities and unused / not fully used resources),

- shortening delivery cycles, reducing the negative impact on the environment (of processes and products).
- Meeting customer requirements by suppliers can therefore turn into mutual benefits, the achievement of which is based on building cooperation. This cooperation is based on building trust between partners and ensuring continuity of processes in supply chains.

## ANALYSIS OF CUSTOMER SERVICE QUALITY MANAGEMENT IN IMPLEMENTATION OF TSM KODAWARI AT TAM WORKSHOP

*Abstract:* Toyota Astra Motor (TAM) workshop is a Toyota vehicle repair shop that provides vehicle repair services. Currently the service is not only in the form of quality results from vehicle repairs, but other services such as vehicle completion time, repair costs and personal service.

*Research aims:* For Toyota, all of these services are summarized in the TSM Kodawari which is the basis of service, but the high expectations of customers make every workshop must continue to make continuous improvements.

*Design/Methodology/Approach:* For this reason, it is necessary to analyze the TAM workshop service which has been carried out using the Service Quality (Servqual) method, which is a direct assessment from customers and employees of the TAM workshop which is seen as gap 1 and gap 5 with the aim of reinforcing the already good service to continue to achieve customer satisfaction.

*Research findings:* Human resource management approach will also be given to sharpen the discussion of research results. Improvements in gap 1 are in the tool and method factors on the E2 dimension and in gap 5 on the method factors on the E3 dimension.

*Theoretical contribution/Originality:* Suggestions are given to the research findings to continue to achieve customer satisfaction.

**Keywords:** workshop, gap, customer, kodawari, servqual

### 1. Introduction

The rapid development of the automotive world in Indonesia has made many automotive repair shops continue to make improvements in their services along with service users who are increasingly critical and have high expectations for repairing their vehicles and the services provided by the workshops.

Customer dissatisfaction can have an impact on the loss of customers and can even change vehicle brands. For this reason, it is very important to make continuous improvement and innovation to create customer satisfaction.

Toyota-Astra Motor (TAM) Workshop is a car repair shop that serves the repair of Toyota brand vehicles, which is the largest automotive company in Indonesia, located in Sunter, Jakarta. With the increasing number of requests for periodic vehicle repairs and

other Toyota vehicle repairs, TAM Workshop must continue to improve customer satisfaction.

Based on the existing service standards at TAM Workshop, TSM Kodawari makes services that are directed and controlled, but actually, complaints are still obtained from the Post Service Follow Up (PSFU) TAM Workshop which is part of the service to find out customer responses after 3 days of the vehicle. has been repaired by calling directly to the customer making the need for improvement in the services provided by TAM Workshop. It is necessary to conduct research to determine the extent of the TAM Workshop services that have been provided in accordance with the service dimensions contained in the Service Quality (Servqual) method, by providing direct questionnaires to customers.

The objectives of this research are:

- 1) Measuring the perception of workshop management/employees on the expectations of workshop service users.
- 2) Measuring the perceptions and expectations of service users on service quality.
- 3) Measuring the size of the gap between the perceptions of the management/workshop employees and the expectations of service users regarding the quality of workshop services.
- 4) Measuring the size of the gap between perceptions and expectations of service users regarding the quality of workshop services.
- 5) Provide suggestions for improvement of service quality based on TSM Kodawari.

Theories from experts on quality management, especially regarding service quality and human resource management, as well as the results of previous research within the last 3 years will be the main

reference in this research. The most fundamental difference in this research compared to research in the field of quality management, especially service quality, is the use of the TSM Kodawari which is the basis for services that must be obeyed in the TAM workshop as one of the tools to discuss the results of this research.

## **2. Literature Review**

Human Resource Management (HRM) and Service Quality. Previous experts in textbooks on HRM and quality management as well as the majority of research on quality management concluded that HRM and service quality are two things that greatly influence organizational performance. Without good management of resources (including human resources), it will not produce the company's performance as expected. And one of the company's performance will be obtained from consumer satisfaction from the high quality of service. To obtain high quality services, the aspect of human resources plays a very important and very central role.

From the results of previous research, it was revealed that there was a positive and significant relationship between service quality, employee satisfaction and loyalty. Good service quality is obtained from high satisfaction and loyalty from employees and this all increases the effectiveness of human resource management (HRM) which in turn will improve the company's performance. In the results of this study also that customer satisfaction also has a positive relationship with service quality, employee satisfaction and loyalty to effective HRM. Customer satisfaction is the key element that increases satisfaction and employee loyalty that increases effectiveness of human resources (Decha, Khlungsaeng, Bousri & Pulphon, 2020).

The results of other studies show that there is a close relationship between service quality and HRM practices, where good and effective HRM practices can significantly improve service quality which can increase the company's competitiveness in general, good HRM practices can also contribute to human resource development which aims to maintain competent employees and develop employee capabilities needed to meet a high quality of service, then good HRM practices will produce highly competent employees employees, committed to learning, and higher job satisfaction, thus achieving higher levels of productivity and in turn effectively meet organizational goals (Khassawneh & Mohammad, 2021).

Other research results also show that there is a statistically significant relationship between products (either goods or services), company policies, solving problems that occur in the field, personal interaction and empathy from employees towards customers, the benefits felt by the customer from the service/product, the dimensions of service quality and and customer satisfaction, the most important thing is that customers think that products must be of good quality, develop and provide recommended services quality factors efficiently and effectively help in obtaining customer satisfaction that leads to customer loyalty, to create customer loyalty, the company must understand customer perceptions of dimensions of service quality so that this service quality dimension can be used as a strategy reference in meeting customer needs (Rashid & Rokade, 2019).

Other studies that discuss the relationship between service quality and customer loyalty in Nigerian hospitality shows that there is a positive relationship between service quality and customer loyalty, this study also found a positive relationship between the existence of a customer's brand with customer loyalty where the customer brand be a mediating factor of the relationship between service

quality and customer loyalty. where is the service quality has a direct effect on hotel customer loyalty while customer brand also affects customer loyalty even though not directly, this means that hotel managers must focus on improving service quality because it has a direct effect on customer perceptions which in the long term can increase customer loyalty (Silas, Dung & Bagobiri, 2022).

In general, from all research references, three of which we have described above, it shows that human resource management is indeed a very important aspect in improving the quality of management. What distinguishes this research from previous research is that we analyze the implementation of TSM Kodawari through the Servqual method approach, in contrast to other studies that have not analyzed the implementation of TSM Kodawari through this Servqual method approach.

Servqual. Measuring service quality means evaluating/comparing the performance of a service with a set of predetermined standards. Servqual is a multi-item scale measurement model that is intended to measure the expectations and perceptions received by customers, and the gaps that exist in the service quality model. Servqual defines the evaluation of customer quality in terms of the gap between the level of expectations and the level of perception received by the customer. Measurement can be done with a Likert scale, where respondents just choose the degree of agreement / disagreement with statements regarding the delivery of service quality. Measurement of service quality must be carried out and improved periodically. So, the questionnaire used must be continuously developed and adapted to the situation at hand. Servqual has several drawbacks. Servqual assumes that customer satisfaction is linearly related to the performance of service attributes. The implication is that low customer satisfaction results from low attribute performance, therefore these low

performance attributes are the focus of improvement efforts. This assumption is not entirely correct. Focusing on improving certain service attributes does not always lead to increased customer satisfaction if these service attributes are not considered important by customers. On the other hand, customer satisfaction can sometimes be improved only by a small increase in a pleasant service attribute that the company did not expect to provide. In addition, Servqual provides important information about the gap between the level of customer expectations and the level of customer satisfaction, but Servqual cannot provide a solution on how the gap can be overcome. In services, there are main dimensions needed by every service user. Simplification of these dimensions can be divided into 5 main dimensions, namely:

- 1) Reliability, related to the company's ability to provide accurate service from the first time without making any mistakes and deliver its services in accordance with the agreed time.
- 2) Responsiveness, with regard to the willingness and ability of employees to help customers and respond to their requests, and inform when it will be provided and then provide prompt service.
- 3) Assurance, namely the behavior of employees is able to foster customer trust in the company and the company can create a sense of security for its customers. Assurance also means that employees are always courteous and have the knowledge and skills required to deal with any customer questions or concerns. This dimension has four sub-dimensions, namely:
  - a) Competence, expertise and skills that must be possessed by service providers in providing their services to customers.
  - b) Credibility, honesty and responsibility of the service

provider so that customers can trust the service provider.

- c) Courtesy, ethics of courtesy, respect and friendliness of the service provider to its customers.
  - d) Security, a sense of security, a feeling of being free from fear and free from doubts about the services provided by the service provider to its customers.
- 4) Empathy, means the company understands the problems of its customers and acts in the interests of customers, and gives personal attention to customers and has safe operating hours.
  - 5) Tangibles, relating to the attractiveness of the physical facilities, equipment and materials used by the company.

And in the service gap there are 5 main gaps, in the research at TAM Workshop the gaps that can be studied are gap 1 and gap 5, namely:

- 1) Gap 1, between customer expectations and management perceptions (knowledge gap). This gap means that the management perceives customer expectations of service quality inaccurately
- 2) Gap 5, between the perceived service and the expected service (service gap). This gap means that the perceived service is inconsistent with the expected service.

TSM Kodawari. TSM Kodawari is a program to realize/realize an accurate response to customer requests and meet daily vehicle delivery times by consistently providing "minimum standards" of high-quality, accurate service based on customer expectations and desires. TSM Kodawari is applied to every Toyota dealer around the world through kaizen assessment and activities, dealer execution and carrying out the 77 kodawari items set by Toyota aimed

at six service operations in total from maintenance reminder & appointment to follow-up after service. The six service operation processes are:

- 1) Maintenance Reminder & Appointment.
- 2) Appointment Preparation.
- 3) Reception.
- 4) Production.
- 5) Submission.
- 6) Follow-Up After Service.

### 3. Research Method

A research method is indispensable in a scientific research plan. This method must be arranged systematically and directed to get research results that are right on target in accordance with the problem and research objectives. The steps that will be carried out in the process of this research later, are:

- 1) Research studies are the initial stage to conduct this research, where this research understands the problems that arise in the place where it will be used as a case study.
- 2) Literature study is carried out to obtain various information about theories that can be used to solve the problems faced, as well as to develop insightful knowledge from researchers. Literature study is done by reading scientific journals that are relevant to the problems at hand. The concepts used in this study include customer satisfaction, service quality, TSM Kodawari TSM and improvement of the concept of 7 Basic of quality tools.
- 3) The field study aims to observe the object to be studied, namely the services at the TAM workshop.
- 4) Problem formulation is an activity carried out to formulate, namely the problems that occur at this time are the incompatibility of customer expectations for the services provided by the TAM workshop or the need for

improvement in adjusting Toyota's service standards to higher customer expectations. This can be seen from the results of PSFU which states that service dissatisfaction is quite high because complaints or customer requests/expectations have not been resolved, both technically and non-technically.

- 5) Research objectives. At this stage the researcher formulates what the research objectives are.
- 6) The research design, there are 3 designs, namely:
  - a) Research model design, namely modeling services into 5 service dimensions
  - b) Identification of the research model, which describes each service dimension according to the Kodawari items.
  - c) The design of the assessment mechanism, namely how to assess the service in the form of a questionnaire.
- 7) Preparation of questionnaires, namely making questionnaires for employees, customers and levels of interest related to gap 1 and gap 5.
- 8) Determination of the number of samples, using the formula and characteristics of the study can be determined the number of samples as many as 100 samples. Questionnaires for customers were made into a questionnaire of perceptions-expectations and questionnaires of importance. As for employees, the questionnaire is about their opinions regarding customer expectations
- 9) Data collection is the collection of primary and secondary data.
- 10) Validity test, which is to test whether the data obtained is valid
- 11) Reliability test is to test whether the data obtained is reliable

- 12) Analysis and Discussion, namely analyzing data that is valid and reliable to be studied using theories that are relevant to the research problem and the discussion provides recommendations so that the results of this research can be applied in the company.
- 13) Conclusions and suggestions, namely concluding regarding the purpose of this research and providing suggestions for steps that can be taken to carry out the recommendations for the company.

#### 4. Result and Discussion

From testing the data from the questionnaire results, it is found that the data is valid and reliable. From the data processing of the questionnaire results obtained results for the level of customer importance, customer expectations value, customer perception value and employee perception value as shown in the following tables:

**Table 1.** Level of Customer Importance

DIMENSION		QUESTION	LEVEL OF IMPORTANCE
TANGIBLES	T1	Clear directions or information to make it easier for customers to service vehicles	4.5
	T2	Cleanliness of customer toilet facilities	4.62
	T3	Quality of entertainment (Wifi, Audio, internet service, kids corner, etc.) in the waiting room	4.64
	T4	Quiet atmosphere (not noisy) in the waiting room	4.54
RELIABILITY	R1	Ability of repair shop workers to analyze problems correctly	4.78
	R2	Adequate and good service equipment and supplies.	4.74
RESPONSIVENESS	RS1	Workshop staff provide clear and easy-to-understand information	4.68
	RS2	Explanation of officers regarding vehicle maintenance or repairs carried out and estimated costs	4.66
	RS3	Availability of workshop staff in serving customers	4.79
	RS4	Punctuality in vehicle delivery ( <i>on time delivery</i> ) after repairing the vehicle	4.69
ASSURANCE	A1	Knowledge and expertise of workshop workers	4.58
	A2	Discipline of workshop workers	4.72
	A3	Courtesy and friendliness of repair shop workers	4.64
	A4	Honesty of repair shop workers	4.78
	A5	Attitude of workshop workers towards maintenance and vehicle repairs	4.72
	A6	Staff explanation regarding job guarantees when delivering vehicles	4.78
EMPATHY	E1	Ease of contacting TAM <i>Workshop</i> if there are complaints	4.79
	E2	Ease of meeting <i>Service Advisors (SA)</i> or other workshop staff	4.5
	E3	Availability of written information what matters to the customer	4.6
	E4	Careful attention to the customer	4.78

	RS2	Explanation of officers regarding vehicle maintenance or repairs carried out and estimated costs	4,65
	RS3	Availability of workshop staff in serving customers	4,67
	RS4	Punctuality in vehicle delivery ( <i>on time delivery</i> ) after repairing the vehicle	4,79
ASSURANCE	A1	Knowledge and expertise of workshop workers	4,44
	A2	Discipline of workshop workers	4,37
	A3	Courtesy and friendliness of repair shop workers	4,53
	A4	Honesty of repair shop workers	4,60
	A5	Attitude of workshop workers towards maintenance and vehicle repairs	4,33
	A6	Staff explanation regarding job guarantees when delivering vehicles	4,53
EMPATHY	E1	Ease of contacting TAM <i>Workshop</i> if there are complaints	4,60
	E2	Ease of meeting <i>Service Advisors (SA)</i> or other workshop staff	3,79
	E3	Availability of written information what matters to the customer	4,30
	E4	Careful attention to the customer	4,51

Source: Data Processing

Value of service quality:

- a) Gap 1: This gap is the difference between employee perception scores and customer expectations. The highest gap is obtained in the service dimension E2
- b) Gap 5: This gap is the difference between perception and expectation scores multiplied by the level of importance. The highest gap is obtained in the service of the E3 dimension.

## 5. Discussion

Servqual score at Gap 1: From the data processing, the highest gap value in gap 1 is the service dimension E2 or the ease of meeting a Service Advisor with a score of -1.03. This happens because:

- 1) There is no application that supports making technical reports on the computer in the Service Advisor room
- 2) Customers have difficulty meeting Service Advisors because customers are not directed when entering the Service Advisor room, this happens because of the absence of an officer who directs customers, this task is usually carried out by security officers but at the same time security officers are parking the customer's vehicle

Servqual score at gap 5: From the data processing, the highest gap value in gap 5 is the service dimension E3 or the availability of written information that is important for customers with a score of -2.27. This happens because:

- 1) There is no standard for writing a good and clear report because the technician manually fills in the results of his work, sometimes the writing is not clear
- 2) Lack of availability of written information that is important to

customers, this happens because there is no job advice obtained from technicians not known by customers because they are included in the Service Advisor report

From the results of the Servqual score on the service dimension E2, you must create a system/application for making technical reports making SOPs involving drivers in directing customers who come when security officers are busy.

From the results of the Servqual score on the dimensions, there needs to be a rule that technicians must write the results of his work in capital letters and complete and always include complete information whether there is a job suggestion or no job suggestion.

Apart from the analysis of the data obtained from the results of data processing and direct observations in the field, it can be seen that the human resource factor plays a very important role in producing good service performance in addition to equipment (in this case a computer) and procedures (SOP). The number and qualifications of human resources who provide services must be in accordance with service needs, in this case it appears that the number of employees serving is still limited where security officers are still on double duty to park vehicles and serve advisors and technicians have not done their job perfectly in terms of job reporting. The number and qualifications of good service personnel will improve service performance which will also foster customer loyalty and will ultimately improve the company's overall performance.

## 6. Conclusion

The conclusions that can be obtained from this research are:

- 1) The perception of the workshop employees on the expectations of service users or customers can be

measured according to the dimensions of service quality (Servqual) with the highest value on the T2 dimension. and the lowest value on the E2 dimension.

- 2) Perceptions and expectations of service users or customers on service quality can be measured in accordance with the dimensions of service quality (Servqual) with the highest value of perception on the RS2 dimension while the lowest perception on the E3 dimension. The highest value of expectations is on the E4 dimension and the lowest value of expectations is on the A2 . dimension
- 3) The gap that occurs between the perception of the management/workshop employees on the expectations of service users regarding the quality of workshop services or gap 1 can be measured by the highest value on the T2 dimension and the lowest dimension on the E2 dimension.
- 4) The gap between perceptions and expectations of service users regarding the quality of workshop services or gap 5 can be measured with the highest value on the RS2 dimension and the lowest dimension value on the E3 dimension.
- 5) Suggestions for improving research results to improve service quality based on TSM kodawari

Suggestions/recommendations that can be given are as follows:

- 1) The company's Information Technology Department must

provide the system/application needed by the Service Advisor and move the computer equipment that has been used to make technical reports located in the control room to the Service Advisor room.

- 2) Make standard SOPs regarding driver officers to help direct customers who come by greeting first, politely and warmly by inviting each officer to a meeting to discuss problems and making SOPs.
- 3) Make a SOPs for writing the results of work by technicians in the form provided in capital letters and fill in completely regarding the results of the work and publish it with a signature, this shows that each technician understands and agrees with the new SOPs.
- 4) Make SOPs for completing work which are required to include all information regarding work suggestions even though there are no suggestions that can be proposed to the information system on the computer application so that customers can get information on documents that customers get regarding their vehicles after repairs whether there are work suggestions or not as customer references for further repair.
- 5) For further research, it is hoped that this research on the implementation of TSM Kodawari TSM can be more comprehensive by expanding its scope to other parts not only in the workshop or adopting TSM Kodawari in companies other than Toyota Astra Motor.

## ENSURING THE COMPETITIVENESS OF INDUSTRIAL ENTERPRISES IN TERMS OF METHODS FOR ASSESSING THE QUALITY OF INDUSTRIAL PRODUCTS

**Abstract:** *The article examines the model of the quality management system based on international standards ISO 9000 series is generally recognized in the world. It is being implemented at enterprises of all forms of ownership operating in various countries and sectors of the economy. The standard has gained such wide popularity due to its versatility and approaches to quality management, which have shown their effectiveness and efficiency in practice.*

*In the modern world, the basis for ensuring a competitive advantage of an enterprise in the market is the continuous improvement of its management system and products. The ISO 9000 series of standards focuses the organization on continuous improvement and the fullest satisfaction of the requirements of all stakeholders. The quality management system is an important factor of competitiveness. The presence of a quality management system at the manufacturer means, in market language, the ability of this enterprise to meet the requirements of consumers, regulatory requirements from the state and the requirements of the organization for its own activities. In accordance with the General provisions of the standard, this is the main purpose of the quality management system. Modern enterprises operate in a constantly changing market environment. Only those companies that can quickly adapt to changes in the external environment can survive in the competition. In this regard, the quality management system should be flexible and quickly "adjusted" to changes in the requirements of the parties interested in the company's activities. Only such a management system can become a useful tool in the hands of the company's management.*

**Keywords:** *standardization, product quality, quality management system, products, competitiveness, economic efficiency.*

### 1. Introduction

The quality of products is determined by the generalized properties of its production

(reliability, durability, maintainability), which can satisfy certain needs for further operation.

A number of properties characterizes the quality of a product, and properties are indicators that quantitatively characterize one or more properties of this product. Often, density, resistance, etc express the properties of products and their quality criteria.

The quality of mechanical engineering products is an indicator of scientific and technological progress and production culture in mechanical engineering. The level of product quality in the machine-building industry has an important place, which is associated with the need to increase the competitiveness of products in the domestic and world markets. Ensuring and improving the quality of products in mechanical engineering is a complex task. Its solution is to improve the design of machines and their components, the use of new materials and automation of technological processes.

Product quality is a relative concept that can be analyzed quantitatively, that is, by comparison with basic products of similar purpose. The relative component of product quality, which is based on its comparison with the corresponding set of basic indicators, is called "product quality level". The values characterizing the properties of product quality are called quality indicators. They can be absolute, relative or specific. A product quality indicator that can take into account one of its properties is called a single indicator, two or more properties are called complex.

The criterion of the quality level of the product is an integral quality indicator that determines the ratio of the useful total effect of the product to the total cost of its production [1]. Product quality management is carried out through systematic control of compliance of quality indicators with standards, technical characteristics, regulatory documents, targeted impact on the quality of documentation, equipment, tools, materials, components, on the level of qualification of manufacturers.

## **2. Literature review**

The problem of the quality of mechanical engineering products acquires a special role in modern times. The quality of products is the main lever for increasing competitiveness in world markets, as well as one of the main components of economic progress [20]. A special place in the problem of ensuring the quality of mechanical engineering products is occupied by mechanical engineering technology, because new progressive design developments and research are implemented through it.

Mechanical engineering technology is a branch of science about the laws of the processes of manufacturing machines of the required quality, in the prescribed quantity and timing with minimal costs of living and materialized labor, material and energy resources [1]. The main task of mechanical engineering technology is to ensure the planned quality of products in its manufacture. The most effective approach to solving this problem is the technological provision of optimal parameters for the specified operating conditions of the state of the surface layer, the accuracy of the manufacture of parts and assembly of machines.

During use, the surface layer of the product is subjected to the strongest physical, chemical and mechanical effects. Therefore, the destruction of parts in most accidents begins with the surface layer [5]. Based on this, solving the problem of technological quality assurance of parts, it is necessary to develop such technological characteristics that will be able to provide the required parameters of the state of their surface layer, determined by the working conditions of the part, as well as the specified processing accuracy. Special attention should be paid to the formation of the surface layer of parts with various processing methods, the influence of processing methods and the state of the surface layer on the basic

operational properties of machine parts operating under various loads, normal and high temperatures, in non-aggressive and aggressive environments. Attention should also be paid to the basic concepts and indicators of product quality, characteristics of the quality management system and certification of products based on international standards ISO 9000.

It is also important that in recent years the issue of ensuring the quality of machine-building products in developed countries is no longer a concern of individual companies, but is considered as a national issue. For example, in Japan, this issue is considered a major national problem, the United States annually holds a quality month, the Swedish government sponsors a nationwide campaign to improve product quality, and the Netherlands is developing a National five-year plan to improve the quality of products and components. Special attention to the quality of products in developed countries is due to changes in conditions, forms and methods of production due to increased competition in places of sale between leading companies in different countries. Most countries spend a lot of effort on improving the quality of their products, thereby determining their authority and position on the world market, in the fight against competitors.

The problem of ensuring the quality of manufactured products in mechanical engineering is particularly acute in Russia. This problem arises even in a directive economy, when all efforts to ensure and improve the quality of products are planned and controlled by the state [3]. However, at the same time, consumer requests are very poorly taken into account, and the quality of the products themselves is discussed according to the requirements of its consistency with regulatory documents, which, in turn, often lag behind the requirements and wishes of consumers. With a monopoly of producers and the absence of

strong market incentives for qualitative growth-competition - they are not interested in improving the quality of products, spending additional financial resources for these purposes. In this regard, the situation with product quality is aggravated by a growing shortage of goods, when demand increasingly exceeds supply and consumers, deprived of choice, are ready to buy goods of any quality and at set prices. That is why the problem of ensuring the quality of products is important and serious for the development, progress and prosperity of the country's economy.

### 3. Methodology

Market relations have exacerbated the problem of quality and competitiveness of manufactured products. An effective means of solving this problem is the implementation of the provisions of the ISO 9000 series of international standards, which reflect the concentrated world experience in ensuring product quality, and the main emphasis is on measures that guarantee stable output [2].

To achieve this goal, the organization must keep under control all technical, administrative and human factors that affect the quality of products. In order to achieve the goals defined by the company's quality policy, such a quality system should be developed and implemented, which covers 2 interrelated aspects:

- 1) consumer requests and expectations;
- 2) requests and interests of the organization.

Improving the quality of products is a constant well-coordinated work aimed at improving both the technical level of product quality and the quality of its manufacture, as well as improving production technologies and the quality system as a whole. The process of improving the quality system is recommended to be carried out in the

following sequence:

- determine the direction of improvements and the means to implement them;
- to investigate the characteristic features of the problem;
- analyze the collected information, outline changes and, if necessary, experimentally check the options for changes;
- make changes to the improvement object;
- to analyze the functioning of the improvement object after making changes;
- document the found solutions for improvements.

The ISO 9000 standard defines key terms, interprets contractual terms, types of standards, and contains the basic principles for implementing the management's quality policy. It establishes and separates the rules for the use of quality assurance models related to the contract (ISO 9001), formulates three main tasks of the manufacturer in the field of quality, namely:

- 1) to achieve and maintain the quality of products at a level that is able to ensure the continuous satisfaction of the goals of consumers;
- 2) provide the management with confidence that the required quality is achieved and maintained at a given level;
- 3) to provide the consumer with confidence that the intended quality of the supplied products is being achieved or will be achieved; ensuring confidence may mean mutually agreed requirements for providing evidence, if this is provided for by the contract [8].

Methods of assessing the quality of industrial products involve an assessment of the experience and business reputation of business entities. The regulatory framework for this can be the standard: GOST R

66.0.01-Assessment of the experience and business reputation of business entities [21,22]. The standard also approves requirements, models and indicators for assessing the business reputation of companies based on their operational experience. The standard provides a holistic and objective approach to the ranking and selection of organizations during tenders or competitions, and also participates in the assessment of the reputation and financial success of the company. The standard assumes the use of a factor model. A factor system model is a mathematical formula expressing real connections between the analyzed phenomena.

In general, it can be represented as follows:

$$y = f(x_1, x_2, \dots, x_n)$$

Where

y - is the effective feature;

x- factorial features that include weight characteristics that are empirical in nature [21,22].

The problem of effective spending of budgetary funds as a tool for assessing the quality of industrial products in a difficult economic situation is becoming more and more urgent. This determines the importance of evaluating the effectiveness of the use of funds when placing a state and municipal order. The form of a state or municipal order is defined by Article 72 of the Budget Code of the Russian Federation and the holding of tenders and tenders on the basis of Federal Law No. 223-FZ [23]. There are two options for effective spending of budget funds: According to the first option, the achievement of the necessary result occurs using the least funds. According to the second option, the lowest result is achieved using a certain amount of funds. This principle is sometimes implemented in a tender, where the evaluation of proposals takes place according to various criteria, and the goal is to conclude a contract on the best

terms. In accordance with Federal Law No. 44 dated 05.04.2013-"On the contract system in the field of procurement of goods, works, services for state and municipal needs", customers are given the opportunity to take into account factors of experience and business reputation when choosing a contractor during procurement within the "business reputation" criterion of a procurement participant[24]. The standard enables public and private customers to apply professional tools that simplify the procedure for pre-selection of bidders by establishing an objective conformity assessment procedure approved in the Methodology for Assessing the Business Reputation of a construction organization. [21,22].

The Law regulates relations that focus on ensuring state and municipal needs in order to increase the efficiency and effectiveness of procurement of goods, works, services, ensuring transparency and transparency of such procurement, preventing corruption and other abuses in the field of such procurement. The Budget Code of the Russian Federation, defining the efficiency and economy of the use of budget funds as one of the principles of the budget system, establishes the obligation of recipients of budget funds to use budget funds effectively in accordance with their intended purpose [23].

Conducting an assessment of experience and business reputation allows you to conduct:

- comparison of the company's level of development with competitors, adequate positioning of itself in the market;
- independent confirmation of the competence and professional success of the organization, including for participation in tenders for public and private orders within the framework of 44-FZ and 223-FZ;

- assistance to consumers in the competent selection of suppliers of goods, services and works;
- improving the competitiveness of business entities;
- formation of a business reputation management system [23, 24].

Special attention in the ISO 9000 standard is paid to the conclusion of a contract, which, as a rule, is preceded by an assessment of the quality system in force at the enterprise in order to determine the supplier's ability to meet the requirements of standards and additional technical requirements for products or services specified in the technical conditions of the contract.

When developing the international standard ISO 9001:2015, a risk-based approach is used to create a QMS, which is one of the key changes in the new version of the standard. The basics of risk management in the updated version of the standard is integrated into the quality management system as a whole, and taking risks into account when making decisions turns preventive actions into part of the process approach. Risk management activities create the basis for improving the effectiveness of the quality management system, achieving better results and preventing adverse consequences. The organization needs to identify the risks and opportunities to be considered, as well as plan and implement actions to reduce them and evaluate the effectiveness of these actions [4].

However, not all processes in an organization have the same level of risk in terms of their impact on the organization's ability to achieve its goals, and the consequences of inconsistent processes, products, services or systems are not the same for different organizations. In some organizations, the consequences of providing substandard products or providing substandard services can cause only minor inconvenience to customers, while in other

cases, substandard products can lead to far-reaching consequences, up to a fatal outcome[18]. Thus, risk-oriented thinking means that risk must be taken into account quantitatively when determining the seriousness and depth of the approach to planning and managing the quality management system, its processes and activities.

The text of the standard assumes the application of a risk-based approach at all stages of the functioning of the quality management system.

Risk should be considered not only as a negative phenomenon for the enterprise, but also as a positive opportunity to find directions for improving the production process. ISO9001:2015 does not require a full formal risk assessment after completion of the "risk registration" or any other document[10]. As a useful, reference document on risk-based decision-making methods, GOST R ISO 31000-2010 "Risk management. Principles and Guidelines".

Therefore, in the conditions of mandatory transition to the new version of the ISO9001:2015 standard, interest in the use of risk-oriented methods in the construction of QMS will increase, and the developed methods and tools can be widely used. By improving management, ensuring high quality of products and services, increasing customer confidence and satisfaction, increasing the competitiveness of organizations using risk-based thinking.

In modern conditions, it is necessary to improve the quality of products. The quality of modern enterprises is becoming one of the decisive factors for increasing production efficiency and the overall intensive development of the economy[17]. In addition, the production of low-quality products at individual enterprises and in the national economy as a whole caused huge economic losses. Quality determines the level of competitiveness of a modern

enterprise by one in the conditions of increasing competition for sales markets (Galinovsky A.L., 2018).

That is why improving the quality of products is the most important goal that can increase production efficiency. Production efficiency, in turn, is determined by the ratio of the results obtained and production costs [6].

Methods. The need to assess the quality level of industrial products arises during its planning, certification and control (Alekseenko, A.A., & Ratner, S.V., 2014).

When assessing the technical condition of homogeneous machines (parts), a differential, complex and mixed method is used, for heterogeneous machines (parts) – the method of quality indexing. When it becomes difficult to assess quality by quantitative indicators, they resort to expert assessments (Dotsenko, B.I. 1983). The differential assessment consists in the fact that individual indicators are calculated according to the formula:

$$Yk_i = \frac{Pi}{Pi_{\text{bas}}},$$

where Pi is an indicator of the quality parameter of the machine being evaluated; Pi<sub>bas</sub> is the corresponding quality indicator of the basic machine sample.

If the quality indicator has limitations (Pd<sub>i</sub>), then the quality level is determined by the formula:

$$\acute{O}k_i = \frac{Pi - Pd_i}{Pi_{\text{bas}} - Pd_i}$$

For a particular type of machine, all quality indicators are divided into 2 types: main and secondary. The technical level of the machine being evaluated is considered to be lower than the base machine if at least one of the main indicators is lower than a similar base indicator [9]. If the indicators are difficult to divide into main and secondary,

then the assessment is based on complex or mixed quality assessments.

As a comprehensive assessment, a single indicator (P), an integral indicator (Ppi), a weighted arithmetic average (U) or a geometric (V) quality indicator can be used, thus:

$$U = \sum_{i=1}^n m_{iu} \cdot P_i; V = \prod_{i=1}^n (P_i)^{m_{iv}}$$

where  $m_{iu}$   $m_{iv}$  - are the weighting parameters of the quality indicator; n is the number of indicators.

For evaluation by a mixed method, some indicators are combined into groups, while others are not combined. After that, they are compared with the group or individual indicators of the basic variant.

The quality level of heterogeneous machines is assessed by the quality index, which is found as the ratio of the value of the weighted average quality indicator of the evaluated and the base machine. The defect index can also be used to assess the quality of heterogeneous machines. This complex indicator is a weighted average defect rate, which is calculated by the formula:

$$U_{\bar{a}} = \sum_{i=1}^N \alpha_i R_{\bar{a}i}$$

where  $\alpha_i$  - is the weighting coefficient of this type of machines;  $R_{\bar{a}i}$  - is the defect coefficient of machines, which is an indicator of the quality of manufacture of this type of machines; N - is the number of types of machines being evaluated.

Based on the objectives of this assessment and taking into account the significance of the quality indicators specified in the documents for this type of machine, the nomenclature of quality indicators is established [7]. At the same time, international, national foreign and domestic quality standards, documentation for the supply of machines, catalogs, brochures and

standards of manufacturers of this type of machines, patent, competitive and economic documentation are taken into account.

## 4. Conclusion

The quality of products in modern conditions is the most important component of the efficiency and profitability of the enterprise, therefore it is necessary to continue to pay special attention to it [15]. All participants in the production process-from the heads of the enterprise to the specific performers of any operation should be involved in improving the quality of the enterprise.

Improving the quality of products is the most important direction of intensive economic development, is a source of economic growth, is a benefit of social production. In these conditions, the importance of integrated product quality management and production efficiency increases.

The quality management system of various enterprises is individual. However, world science and practice have formed common features of these systems, as well as methods and principles that can be applied to each of them. In this article, the most effective and popular methods capable of assessing the quality level of products were considered [13].

Thus, the level of product quality is a relative characteristic based on a comparison of the values of indicators characterizing the technical and economic perfection of complex indicators of reliability and safety of use of the evaluated products.

The lack of economic efficiency of improving the level of product quality practically does not exist. Even enterprises or companies that produce products that are not of high quality may be interested in improving quality, since this always means conquering new sales markets, expanding production, increasing profits and increasing competitiveness [14]. At the moment, there

is an opportunity to modernize production and improve the quality of products according to all existing indicators. There are enterprises for which improving the quality of products is a secondary task, but the conditions of competition on the world market cause that such enterprises will sooner or later be forced to modernize their production, aiming the work of the enterprise at improving its quality management system [19].

In conclusion, we can conclude that improving the quality of products will always be a positive and cost-effective factor in the development of any enterprise.

## QUALITY TOOLS AND METHODOLOGIES INFLUENCING THE INVESTMENT AND DEVELOPMENT PERFORMANCE IN AEROSPACE INDUSTRY COMPANIES OF THE EUROPE AND NORTH AMERICA

**Abstract:** Previous research has very rarely aimed to examine the influence of the usage of quality tools and methodologies on investment and development performance. This paper aims to fill the gap in research evidence and is focused on the empirical examination of quality tools and methodologies influencing the investment and development performances on a sample of 173 companies operating in the multinational aerospace industry supply chains in Europe and North America. Europe and North America have been chosen due to their companies' very high incomes in the aerospace industry. By using descriptive statistics, hypothesis testing, correlation and regression analysis, the results are obtained as follows. Results show that examined companies in Europe and America differ regarding all observed quality tools and methodologies, but not in investment and development performance indicators. In that area, there are different patterns. There are evidently the highest correlations between TQM and other tools and methodologies in Europe, while there are not any significant correlations with investment and development performance. The situation in North America differs and there is evidently the highest correlation between Kaizen and basic quality tools and it is clear that there are significant correlations between investment and development performance and quality techniques, such as Six Sigma and TQM. To examine possible influences on quality tools and methodologies for investment and development performance in North American companies, regression modelling has been done, but the expected results have not been obtained. Further analysis is recommended to search for influential factors affecting investment and development performance.

### 1. Introduction

The process of creating quality is a complex mechanism whose ultimate goal is the satisfaction of the customer or end user,

starting from the customer requirements transformed through a complex chain of production or provision of appropriate service (Carlgren, 2013). It is followed by continuous quality improvements, which represent processes whose task is to ensure

---

Corresponding author: Vesna Spasojević Brkić  
Email: [vspasojevic@mas.bg.ac.rs](mailto:vspasojevic@mas.bg.ac.rs)

the constant development and improvement of all segments of one or more processes, where successful quality improvement consists of continuous improvements, corrective measures and innovation simultaneously (García-Fernández et al., 2022). Numerous empirical studies have made an effort to look into quality management in various contexts (Alherian et al., 2021; McAdam et al., 2019; Sousa & Voss, 2001; Spasojević Brkić & Mihajlović, 2023; Spasojević-Brkić, 2011). Certain number of available studies focus on the relationship between quality management and performance (Ebrahimi & Sadeghi, 2013; Lakhali et al., 2006; Machado et al., 2019; Pambreni et al., 2019; Saragih et al., 2020; V. K. Spasojevic Brkic et al., 2013; Tambare et al., 2022; Xu et al., 2020). Surveys focused on deployment of quality tools and methodologies are rare. Sousa et al., (2005) were focused on the degree of use of quality tools, since they offer integration between a business's internal activities and performance and its external requirements. Spasojevic Brkic et al., (2013) divided quality tools and methodologies into three groups and analysed relationships between these groups and business performance measures. The aerospace industry deserves

special attention since it is arguably the most obsessively safety-conscious sector with strict quality control standards (Brkić et al., n.d.; Tomić et al., 2012). On the other hand, it is evident that United States and European countries remain the prominent aerospace markets, with sales in the United States of about USD 214 billion, followed by Europe, Canada and Japan (OECD, 2007, 2011). There is an evident research gap and accordingly, this research focuses on quality tools and methodologies for investment and development performance that were neglected in previous research. Moreover, this research examines the aerospace industry and companies operating in Europe and North America. This paper is structured as follows: it starts with an introduction, which is followed by previous research analysis, and continued with methodology, results and conclusion sections.

## 2. Previous research

Detailed analysis of the previous research determined quality tools and methodologies, as well as the investment and development performance measures, as in Table 1.

**Table 1.** Overview of previous research on quality tools and methodologies

Quality Improvement Tool or Methodology/Performance	Description	Previous research
Quality Tools	Check Sheet, Histogram, Pareto Chart, Flow Chart, Cause-Effect Diagram, Run Chart, Scatter Diagram, Affinity Diagram, Relations Diagram, Tree Diagram, Matrix Diagram, Priority Diagram, Arrow Diagram and Process Decision Program Chart	(Spasojevic Brkic et al., 2013; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tari & Sabater, 2004; Tomic et al., 2017; Tomic & Brkić, 2017)
Quality Techniques	Brainstorming, Benchmarking, FMEA (Failure Mode Effect Analysis), QFD (Quality Function Deployment), Cost of Quality, Sampling Plans, Control Charts, Process Capability and Design of Experiments	(Spasojevic Brkic et al., 2013; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tari & Sabater, 2004; Tomic et al., 2017; Tomic & Brkić, 2017)

Quality Improvement Tool or Methodology/Performance	Description	Previous research
Plan–Do–Check–Act (PDCA) Cycle	Utilization of PDCA on everyday basis in all activities	(Dahlgard & Mi Dahlgard-Park, 2006; Du et al., 2008; Ranjan Senapati, 2004; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tomic et al., 2017)
Kaizen	Practice of the incremental improvements in all processes	(Doolen et al., 2008; Lagrosen, 2003; Ranjan Senapati, 2004; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Spasojević-Brkić, Tomić, Perišić, et al., 2020; Tomic et al., 2017)
Six Sigma	Use of the Six sigma methodology for breakthrough improvements	(Dahlgard & Mi Dahlgard-Park, 2006; Foster, 2007; Ranjan Senapati, 2004; V. Spasojevic Brkic & Tomic, 2016; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tomic et al., 2017; Zu et al., 2010)
TQM	Promotion of TQM values in the organization through its activities	(Anil & K.P., 2019; Dahlgard & Mi Dahlgard-Park, 2006; Hackman & Wageman, 1995; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tomic et al., 2017)
Lean Manufacturing	Practice of lean manufacturing including tools such as 5S, Kanban, or Poke-Yoke	(Dahlgard & Mi Dahlgard-Park, 2006; Jungbae Roh et al., 2008; V. Spasojevic Brkic & Tomic, 2016; Spasojević-Brkić, Tomić, Brkić, et al., 2020; Tari & Sabater, 2004; Tomic et al., 2017)

K. Spasojevic Brkic et al., 2013; Spasojević-Brkić, 2011; Zeng et al., 2017; Zhu et al., 2013)

### 3. Methodology

The research covers manufacturing companies in the supply chain of multinational company in the aviation sector, that are located and spread across North America and Europe. The following stages of research are included:

1. Operationalization of research content (questionnaire construction and/or planning of other forms of data collection in the field);
2. Conceptualization of properties and features of the researched problem (trial research on a small sample);
3. Defining, developing and distributing questionnaires and/or other forms of data collection (conducting the data collection process in the field);
4. Setting hypotheses about expected interdependencies within the researched phenomenon of the problem and processing of collected data (setting research hypotheses and testing the set hypotheses with statistical methods);
5. Analysis and evaluation of the research results (if there are certain doubts regarding the conclusions); and
6. Summing up the results and drawing conclusions. Most of the questions in the survey were taken from or constructed on the basis of numerous previous research studies discussed and analyzed in detail in the literature sources in Table 1, which is very important in research of this type. A Likert scale with multiple answers was used, which is a psychometric scale that is today the most commonly used for this type of research and is very often used in surveys, in which respondents determine their level of

agreement or, on the contrary, disagreement with a certain statement or question.

In this paper, the research instrument was delivered via email to exactly 500 production systems and responses were received from 64 European and 109 North American companies.

First, descriptive statistics on the samples from both regions were arranged in order to determine the types of variables.

Then, differences between regions were tested using statistical hypothesis tests depending on variable type to check if differences could be found on all examined constructs.

Afterwards, correlation analysis is done in order to obtain possible regression dependencies between quality tools and methodologies and investment and development performance.

### 4. Results

Descriptive statistics data containing sample sizes; range, minimum and maximum of the average responses values; mean; standard deviation; variance; significance p level and variable type both for European and North American companies are given in Tables 2 and 3. It can be noticed that European data contain one non-parametric variable.

According to the results in Table 2, the Mann-Whitney U test is used for testing the distributions of both populations (Europe and North America), for the variable basic quality tools. Results are given in Tables 4a and 4b. For other statistics, the t test is used, as in Table 5.

a. The significance level is 0.05.				
b. Asymptotic significance is displayed.				

**Table 4b.** Independent-Samples Mann-Whitney U Test

Summary	
Total N	173
Mann-Whitney U	5855.000
Wilcoxon W	11850.000
Test Statistic	5855.000
Standard Error	315.536
Standardized Test Statistic	7.502
Asymptotic Sig.(2-sided test)	0.000

Results show that Europe and America differ in terms of Basic Quality Tools.

**Table 5.** T test for other constructs

Testing differences on...				t	p	Significance
Quality Techniques	Europe	vs	North America	3.513	<0.001	Significant
Plan-Do-Check-Act (PDCA) Cycle	Europe	vs	North America	8.340	<0.001	Significant
Kaizen	Europe	vs	North America	7.668	<0.001	Significant
Six Sigma	Europe	vs	North America	6.420	<0.001	Significant
TQM	Europe	vs	North America	9.273	<0.001	significant
Lean Manufacturing	Europe	vs	North America	9.635	<0.001	Significant
Investment and Development Performance	Europe	vs	North America	1.726	0.086	Not significant

The results in Table 5 show that there is a difference regarding all other tools and methodologies but not in investment and development performance.

In Tables 6 and 7, correlation analysis results are given, for European and North American companies with significance levels of 0.01 (2-tailed) marked as \*\* and significance levels of 0.05 (2-tailed) marked as \*.

There are evidently the highest correlations between TQM and other tools and

methodologies in Europe, while there are no significant correlations with investment and development performance. The situation in North America differs and there is evidently the highest correlation between kaizen and basic quality tools and there is a significant correlation between investment and development performance and quality techniques, as well as with Six Sigma and TQM.

**Table 8.** Regression model for North American companies

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	0.270 <sup>a</sup>	0.073	0.064	0.433588	0.073	8.386	1	107	0.005

a. Predictors: (Constant), Quality Techniques

Coefficients <sup>b</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	2.445	0.315		7.757	0.000
	Quality Techniques	0.296	0.102	0.270	2.896	0.005

b. Dependent Variable: Investment and Development Performances

Subsequently a stepwise regression model of performance depending on quality techniques, six sigma and TQM was set up and tested, where significant correlations were recorded, as in Table 8. However, the expected dependence was not obtained since there is a low coefficient of determination.

## 5. Conclusion

Previous research has focused widely on the influence of quality management on performance indicators, but the influence of quality tools and methodologies on investment and development performance is rarely examined.

This paper aimed to fill an evident research gap and focused on an empirical examination of quality tools and methodologies for investment and development performance in the aerospace industry and companies operating in Europe and North America. Those constructs have been tested on a sample of 173 companies operating in the multinational supply chains in Europe and North America, which are the strongest pillars of the aerospace industry in the world. The questionnaire has been used

as the research instrument.

By using descriptive statistics, hypothesis testing, correlation and regression analysis, it was aimed to explore differences in different cultural settings, such as European and North American and possible influences of quality tools and technique usage on performance levels. Obtained results show that examined companies in Europe and America differ regarding all quality tools and methodologies used but not in investment and development performance indicators. There are evidently the highest correlations between TQM and other tools and methodologies in Europe, while there are not any significant correlations with investment and development performance. The situation in North America differs and there is evidently the highest correlation between kaizen and basic quality tools and there are evidently significant correlations between investment and development performance and quality techniques, as well as with Six Sigma and TQM. To examine possible influences of quality tools and methodologies on investment and development performance, regression modelling has been done, but expected results have not been obtained.

Further analysis is recommended to research influential factors affecting investment and development performance. A larger sample would also be beneficial, along with stronger quantification parameters regarding investment and development performance

## THE ROLE OF THE COST AND QUALITY IN ADDITIVE MANUFACTURING

**Abstract:** *Global competition demands faster and more economically production process, products to be more personalized with modern design, sophisticated and of higher quality. Companies are looking for new solutions and production technologies to achieve these requirements.*

*Although they have been on the market for almost 30 years, it is only in the last decade that additive manufacturing (AM) technologies have reached a certain level of maturity to be accepted in the wide industry. Currently additive manufacturing is in a period of transition from its initial purpose for the rapid prototyping and small series to the serial production of parts. On that path, there are still obstacles that slow it down in the form of costs associated with the production process (machines, materials), the lack of advance process control, traditional approach to R&D, education of engineers and the lack of software integration from design stage to post processing.*

*Main focus of this paper is cost analysis in AM. In this regard paper will give brief overview of some developed cost models which brought significant novelties in the cost models considering the economics of AM and quality. Based on this analysis the paper will present suggestions what should be included in new cost model for production of end usable metal parts produced by PBF technology. Also, some quality inspection methods for AM will be briefly explained.*

**Keywords:** *cost estimation models, additive manufacturing, PBF, quality cost in AM, PBFtechnology.*

### 1. Introduction

From year to year, the market of additive technologies develops with high speed and more and more revenues are generated. Market research indicates that there is room for additional expansion. With such influence, the economic advantages of AM will play a big part on how this technology will be used in the industry, (Liu, 2017). Currently additive manufacturing is in a period of transition from its initial purpose for the rapid prototyping and small series to

the serial production of parts.

This paper presents a part of the research related to the optimization of the production process using new (additive) technologies that provide certain advantages compared to traditional production.

It is indisputable that additive technologies have advantages in relation to traditional production (material removal or injection molding processes) in terms of the speed of prototyping, the possibility of producing ready-made functional parts (end usable parts) and complex geometries and internal

Email: [slobodan.malbasic@mod.gov.rs](mailto:slobodan.malbasic@mod.gov.rs)

structures. Economic justification of AM is analyzed through costs manufacturing as well as the quality of the final product as two indicators that have a key advantage in making initial decision about investment into this technology and their further application in production.

Main focus of this paper is cost analysis for PBF (Powder Bed Fusion). In the official ISO/ASTM standardization body classification, PBF technology is one of the seven categories of additive technologies, in addition to Vat polymerization, material extrusion, binder jetting (BJ), material jetting, sheet lamination (SL), DED - Direct Energy Deposition. PBF technology together with BJ, SL and DED belongs to the group of metal additive manufacturing method. It is based on the application of laser or electrical energy sources to polymer or metal powders,

in a layer by layer manner in a protective atmosphere, where energy source follows predefined computed path.

Having in mind industry big expectations and demands, PBF applications becomes challenging regarding cost, quality and lead time. Cost per part dominates the final decision on whether they will be manufactured traditionally or additively, (Ampower Insight, 2018).

To investigate commercial opportunities for specific AM technology (PBF for metal part production) and provide answer whether this technology is adequate to respond to customer technical and economical demands, scenario where AM technologies has advantages over conventional manufacturing will be further explained, figure 1 (Leary, 2020).

Figure 1. Cost-volume and cost-complexity curves for TM and AM.

Considering traditional manufacturing (TM), with increased number of products costs associated with production process exponentially goes down (economic of scale) and form basis for mass production. As for the part complexity in TM, more part complexities generate higher costs and in that regard there are certain technical limitations beyond which TM is not capable anymore to provide it. On contrary, AM manufacturing cost is not dependent of

production volume and part complexity, figure 1. Cost per part in AM are calculated based on the other parameters what will be explained later in the paper. Based on this simple explanation and graphical representation, is obvious that after some AM volume and complexity threshold (depends of characteristics of the AM and TM processes) AM becomes economically justified and profitable.

This paper is organized as follows. The second chapter analyzes the cost models developed so far with their specifications and quality costs. The following chapter presents a wide range of traditional and modern quality tools for AM, which represent additional cost generators. The next chapter analyzes the production cycle of PBF technology and proposes a new cost model for PBF technology which include quality costs. At the end of the paper, certain conclusions and directions for further research are given.

## 2. Review of the cost model for the AM process

In this chapter, several key/specific cost models related to the PBF process will be analyzed, which have introduced new cost generators as well as quality costs in their formulas. Cost models for AM have experienced their historical evolution, from the first models being related to fixed costs to the new models that are based on the activity-based cost.

For example, (Baumers, Tuck, Wildman, Ashcroft, Rosamond, Hague, 2012) in his model, beside the Activity Based Cost (ABC) estimation approach, for the first time added the cost of the energy consumed in the process. Presented cost model is limited to so called 'well structured' costs (machine, material, labor), while ill structured costs arising from factors such as build failure, machine idleness and inventory expenses are not taken into account.

(Lindemann, Jahnke, Moi, Koch, 2012) also used a ABC estimation approach (cost of the manufacturing is based on the activity duration) and divided cost between building job preparation, building job production, support structure removing and post-process activities. Lindemann et al. (2012) was among the first authors who introduce quality control cost in the post-process activities.

The first author who recognized all the complexity of the PBF process, introduced new cost drivers into the formulation and recognized the problems related to the optimization during the planning stage was Rickenbacker in his paper (Rickenbacher, Spierings, Wegener, 2013). Offered cost model contains seven processes (preparation, build job, setup, building, removal, substrate, post processing), and what makes its model unique are for the first time introduction of the formulas for: cost per part with different sizes, multiple geometries and quantities in the same build job simultaneously. This model, with certain variations, is the starting point for the development of a new cost model that will be presented in this paper.

Another recognition of the role of the quality in the cost model for PBF is presented in paper (Schröder, M. Falk, B. Schmitt, R., 2015) where it is explained as "modern quality management methods for control of the product and process quality" (page 314). His cost model identified seven main processes: design and planning, material processing, machine preparation, manufacturing, post-processing, administration and sales, and quality, which has possibility to apply to different AM systems, such as FDM, SLA, SLS, and Electron Beam Melting (EBM).

In the work (Barclift, M. Joshi, S. Simpson, T. Dickman, C., 2016) for the first time it was proposed the cost model depreciation of the metal powder. All cost models before this model, and for sure almost all cost models that appeared later, consider material cost as fixed cost. Since the metal powder in the PBF process undergo some thermal treatment from heat source (laser or electro-beam) and are used for several times in subsequent processes, initial cost value of the virgin powder is not the same as at the beginning of the process. Study conducted by (Barclift et al., 2016, page 2007) "indicated that cost models applying a fixed material cost can undervalue built parts with

a high-value virgin powder by as much as 3-11% or 13-75% depending on the material and its maximum build cycles in the PBF”.

Some of the new models, for example model from (Lamei, 2021), divided the PBF process on the three activities: pre-processing costs, processing costs and post-processing costs. As for the cost of the activities related to quality, he included testing cost as part of the post-processing costs. Within inspection cost Lamei include all inspection activities for the evaluation of the final product, mainly inspection of dimensional accuracy, mechanical properties, etc. Lamei (2021) included testing (inspection) cost in the post processing phase, after all activities in this phase is completed. The equation are different in case if there is 100% inspection or sampling inspection. This decision is subject of negotiation between manufacturer and customer. If 100% inspection is required equation is:

$$C_T = A \times N + [p \times N \times B]$$

were: CT - testing cost, A -cost of testing one unit (\$/unit), N - Total number of units, p - Probability of a nonconforming unit, B - Cost to repair or replace a single unit.

(Jarrar, Bernard, Belkadi, 2022) presented a cost model consisting of 6 processes (job preparation, machine setup, build job, machine output, post processing, control process) within which he defined key cost generators. In process control was he included the quality control cost (generated through the use of the tools and methods to evaluate different aspects of quality). Jarrar at all (2022) specifically emphasized that post-processing and quality control costs may take up to 50% of the final product cost.

The most comprehensive analysis about quality cost is presented in (Hajalfaud, Baumers, 2020). Hajalfaud and Baumers (2020) also conclude that previously developed cost models did not consider quality costs. So, they made further

investigation about this topic and in their model involved all quality elements along the production chain. Case study showed that about 20% of total cost goes to quality cost.

The authors defined total quality costs (TQC) as function of replacement costs, preventive maintenance costs (C<sub>pm</sub>), inspection cost (C<sub>in</sub>) and revenue from scrap (C<sub>r</sub>) selling in case of failure:

$$T_{QC} = C_r + C_{pm} + C_{in} - C_{sc}$$

### 3. Quality control in AM

Having in mind that AM is finally crossing stage from prototype to production, the process itself must ensure repeatability, consistency, in order to get overall confidence from potential users. In parallel with this it is of the utmost importance to establish standardized quality control process, (Auerbach, 2021).

For this process there are traditional tools adapted for AM and most advanced digital tools in order to respond to all demands coming from AM. Traditional control tools (for Geometrical Dimensioning and Tolerances) mainly register data manually, this job can be labor intensive and not precise enough, and some steps to improve this are needed.

Auerbach (2021) stated that since the AM is characterized as digitalization process, in that sense more modern measuring equipment, the so-called digital tools, must be used.

With the aim of getting higher level of precision and fulfil of standard requirements, different industries and quality control departments turned they attention to Coordinated Measuring Machines (CMMs). It is import to have control tools that can provide interaction with digital environment characterized for AM. Comparison of measured data of final product with CAD models (form design stage) provide new opportunities for data analysis and

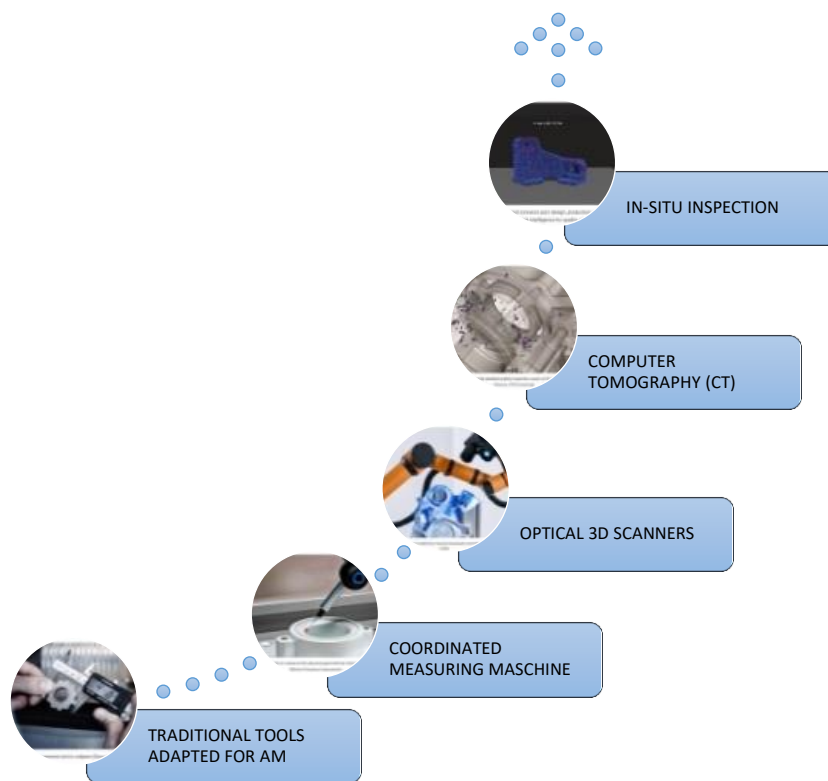

predictions. More advance, non-contact and much faster alternatives to CMMS is 3D scanners.

For the advantages that AM provides in terms of design and complex geometries (lattices structure, and topology optimization), it is necessary to use a special control tool like CT (Computed Tomography). CT is not ideal just for metrology inspection, it have broader capabilities so it can perform non-destructive

testing like internal defects, voids and porosities.

Latest development in the field of sensors, AI, machine learning, cloud computing, closed-loop automation process afford good opportunity for development of in-situ inspection. One of the solutions already available at the market is integration of these tools into the 3D printers.

Exponential curve of the available quality control tools are presented at the Figure 2.

**Figure 2.** Quality control tools in AM

Accoding to (Kim, Lin, Tseng, 2018) in order to improve quality of AM produced parts, new quality control tools should be able to adress issues like: prediction of optimal printing parameter and mechanical properties, real time monitoring and process

control in build job process, feedback interaction between design/printing and part evaluation process, agile part evaluation, high speed fabrication, cyber quality control.

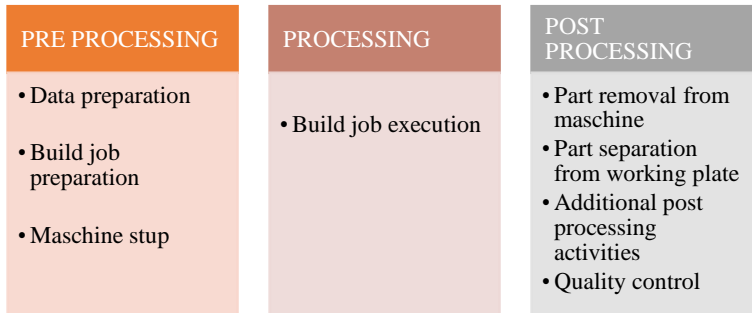

**4. New cost model proposition for PBF technology**

**4.1. PBF production chain**

In order to define the cost model it is necessary to analyze the whole PBF production chain for the fabrication of the metal parts. Briefly explained, the process itself (Figure 3.) begins with the preparation of a 3D model in an adequate software package, then the 3D model is transformed in specialized software to prepare it for 3D

printing (tesselation, build preparation). Next step is loading prepared model in the PBF machine, then goes machine preparation and after that the production of parts layer by layer can start.

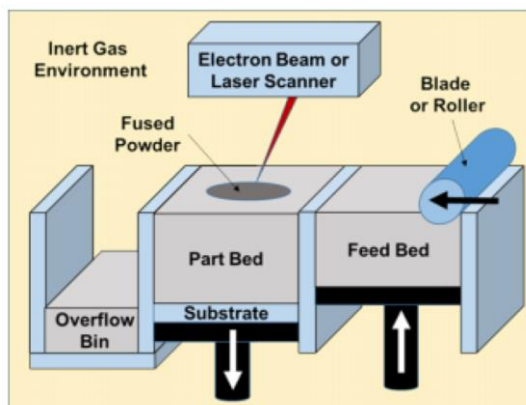

Due to its specificity (support structure elimination, part separation from working plate, residual stress, etc...) PBF process requires post processing activity for improving the overall quality of the end used products. Final parts is submitted to the quality control.

**Figure 3.** PBF production chain

This process requires extensive labor in order to generate a fully-functional component, which additionally increases the

costs of the process. The schematic process of PBF (build job execution phase) is shown in Figure 4.

**Figure 4.** PBF build job execution phase

From the feeding container the thin layer of the powder with recoater are spreading over the surface of the production chamber. Then this layer is exposing to laser or electro beam (Selective Laser Melting (SLM) and Electron Beam Melting (EBM) technology) and after the melting and solidification new layer is formed over the top of the former shaped layer, (Barclift at all, 2016). This process is repeating until the whole part is produced. The size of the part to be produces is limited with the dimension of the production chamber. The rest of the unused and unmelted powder are suing and later using again in the process.

The parameters in this process can be optimized (number of lasers, speed and power of lasers, etc) and thus affect the total production time, production costs as well as the quality of production. The quality of production is especially improved by post-processing activities that are mandatory for PBF technology (stress relief, heat treatment, etc.) and require additional costs.

Advataged that PBF process provide are good dimensional accuracy, repeatability, good material properties with high density as well as possiblity to use wide range of materials and small anisotropy. At the same time there are some disadvantages like need for support structure in order to minimize residual stress, need for post process treatment, staircase effects, etc.

## 4.2. New cost model preposition

Based on the analysis of the aforementioned cost models and discussions with experts in the field of PBF technology, a new model consisting of 3 basic processes (equations) was proposed.

$$C_{total}(P_i) = C_{preproces}(P_i) + C_{process}(P_i) + C_{postprocess}(P_i)$$

In accordance with Figure 3 and Figure 4, within each process there are certain sub-processes that participate in the generation of

total costs and hence the total costs per part can be presented as follows:

$$C_{total}(P_i) = C_{prep}(P_i) + C_{build\ job}(P_i) + C_{setup}(P_i) + C_{build}(P_i) + C_{removal}(P_i) + C_{substrate}(P_i) + C_{postp}(P_i) + C_{quality}(P_i),$$

were:

$C_{total}(P_i)$  – total manufacturing cost per part  
 $C_{prep}(P_i)$  – cost per part for data preparation (CAD model preparation by the operator)

$C_{build\ job}(P_i)$  – cost per part of build job preparation (activities like part orientation, define support structure, model slicing into the cross-sections, all performed by experienced operator in an adequate software tool)

$C_{setup}(P_i)$  – cost per part of setting up the machine (include: machine cleaning and material change, loading of data files, set up of machine parameters, initialization of inert gas, etc)

$C_{build}(P_i)$  – cost per part of building job (it is automated process, cost incurred are related to material, machine, energy, operator and time to build model)

$C_{removal}(P_i)$  – Cost per part of removing working plate from machine (it is labor extensive and hard to manipulate, ask for additional equipment like forklift and jigs/fixtures)

$C_{substrate}(P_i)$  – cost per part of separating parts form working plate/substrate (stress relief for plate, need special tool like EDM for part removal)

$C_{postp}(P_i)$  – cost per part of additional post processing (heat treatment, HIP, shoot penning, etc).

$C_{quality}(P_i)$  cost per part of quality activities (part sampling inspection, material properties analysis, surface and dimensional accuracy, creating quality report cost, quality and process monitoring checks, replacement cost, preventive maintenance cost).

Based on the literature review sub process “Cost of quality activities” consist of two type of activities: 1) labor intensive and sometimes destructive evaluation processes which requires use of digital tools and waste of materials, and 2) control and monitoring activities mainly performed by quality experts.

This paper will not further elaborate each of the above mentioned sub processes equations. Generally speaking cost for every quality activities is calculated as production of time (as duration of activities perform by operator and control tools) and hourly operator rate or hourly cost of using control tools.

## 5. Conclusion and further perspectives

The relevance of the proposed cost model is double. At first place, proposed cost model is a part of an ongoing research focusing on the investigation of economically justification of AM use relative to traditional production and in that process can have decisive role. As second, within AM planning process (and PBF as well) part orientation problems on working plate is essential element which has influence to the final mechanical characteristics of the end-use product. The part orientation problem can be treated as MCDM problem where the cost, among other factors/variables, are taken into the consideration.

In addition to the previously said, this work several cost models in the field of AM have been reviewed, and a cost model using Activity-Based Costing approach is suggested. The main cost drivers within the PBF process chain have been presented and explained, too. Some of the characteristics of the proposed model are as follows:

- Cost in the model should include the entire production cycle for PBF.

- ABC estimation model should be adapted since it is focusing on time duration of the activity what is primary in this model, especially from the labor perspective.
- Build job preparation should be executed in the manner to include all suggestions from (Rickenabuer et al, 2013): mixed part on the build plate, full capacity.
- In addition to (materials, labor, machine costs,...) the new cost model should also include energy cost, powder depreciation cost.
- One of the outcomes should be the cost per part since the companies and customers are interested in estimates of production costs of individual products, and cost per part dominates the final decision on whether they will be manufactured additively.
- Quality cost need to be treated as a separate cost element.
- The proposed model is easy to apply in the quotation process, hence it can support the estimation of costs at early stages.
- Since the proposed model captured all sub processes within PBF it can be used to track the incurred cost of each activity.

Further steps to be performed related to the proposed model:

- Model is focused predominantly on PBF process and for the cost estimation in other AM technologies updates and modification is necessary.
- Quality costs need to be investigate in details and put additionally into the formulation (cost of build failure, cost of redesign due to failures, etc...).

PBF as AM technology for metal end usable part production is very useful and promising technology (considering reduce lead time, producing complex parts, etc) to be consider in forthcoming period as replacement of TM, but before that several aspects, mainly costs and quality, need to be investigate in details. Decision about PBF application whether it is for prototyping process, small or large serial production is subject of further analysis.

Also, it is becoming apparent that more sophisticated quality tools are required and PBF technology is good candidate for application of these quality control tools for real time monitoring, feedback-loops and

predictions of printing parameters.

This paper need to be further expand with case study in order to align presented research with commercial activities in order to get full validation and confirmation of initial posted thesis (commercial opportunities existence for PBF technology for metal part production ). Proposed model can be extended to include cost associated with product lifecycle until the disposal phase. Paper confirmed that not just technical consideration for the AM implantation has to be validated but also economical attributes since it contributes to full commercial success of AM technologies.

## DETERMINE MUSCLE STRAIN OF ASSEMBLY WORKERS BY APPLYING ADVANCED EMG MEASUREMENT

**Abstract:** Contemporary organizations tend to improve the safety and health of workers through the relief of workers from performing strenuous and tiring activities. Musculoskeletal disorders (MSDs) that occur as a result of repeating the same movement over a long period of time, straining and bending the body or performing assembly activities in an ergonomically inadequate body position represent one of the major problems faced by organizations, which further leads to more and more absenteeism of workers from work, reduced productivity and increased costs.

The main aim of the research paper is to show the results of monitoring of muscle activity during the performing of assembly activities in two scenarios - ergonomic and non-ergonomic. The non-ergonomic scenario involves performing assembly activities at a traditional workstation. On the other hand, in the ergonomic scenario, participants perform assembly activities on the proposed ergonomically designed workstation, in the golden zone and in this way bending, stress and stretching of the body are eliminated.

**Keywords:** assembly workstation, EMG, ergonomics interventions, musculoskeletal disorders, safety 4.0

### 1. Introduction

One of the main goals of Industry 4.0, in addition to improving the effectiveness of production processes, is improving safety and health through the achievement of "zero injuries". This goal can be achieved through the elimination of injuries at work, minimization of occupational and work-related diseases, minimization of discomfort and stress. Safety 4.0 represents a shift towards a more data-driven, technology-enabled approach to workplace safety. Intelligent wearable devices and other modern technologies of Industry 4.0 enable real-time monitoring vital signs and tracking

location of workers and identify potential safety risks (for example, detecting exposure to hazardous materials).

The increased automation of the production process and the application of advanced technologies of The fourth Industrial Revolution contributed the relief of workers from performing strenuous and tiring activities. However, many activities cannot be fully automated and workers are forced to perform assembly tasks that are manual and repetitive over a long period of time, which can lead to health problems that in some cases can cause permanent consequences to their health.

---

Email: [marija.savkovic@kg.ac.rs](mailto:marija.savkovic@kg.ac.rs)

Assembly activities in the automotive, engineering and electrical industries are a frequent occurrence. Due to increased effort and muscle strain in workers who perform repetitive, complex, tiring and physically demanding assembly activities in non-ergonomic conditions for a long period of time, musculoskeletal disorders (e.g. carpal tunnel syndrome, joint tendonitis, etc.) and other occupational diseases occur. In a real industrial environment, workers most often perform these activities in a standing position at traditional workstations which additionally contributes to the deterioration of their health condition in the form of lower back pain.

In the member countries of the European Union (EU), musculoskeletal disorders are one of the most common diseases. According to statistics, about 60% of workers suffer from this type of professional illness (Assurance Maladie, 2020; Caroly, S., Major, M. E., Probst, I., & Molinié, A. F., 2013).

This group of occupational diseases is associated with a large number of lost working days during the year, and associated with this are significant financial losses suffered by organizations due to a drop in productivity and increased costs due to absenteeism. According to the study (Warner, M., Baker, S. P., Li, G., & Smith, G. S., 1998) due to the appearance of musculoskeletal diseases, there was a decrease in productivity by 65%.

As one of the main risk factors for the occurrence of disorders of the musculoskeletal system, bad posture and an inadequate ergonomically designed workplace are mentioned in the literature (Alexopoulos, E. C., Burdorf, A., & Kalokerinou, A., 2003; David, G., Woods, V., Li, G., & Buckle, P., 2008). While performing manual repetitive, precise assembly activities, the worker's head and neck are bent forward for long periods of time. This non-ergonomic position of the

body causes pain in the neck and back (Chandrasakaran, A., Chee, H. L., Rampal, K. G., & Tan, G. L. E., 2003; Jonsson, B. G., Persson, J., & Kilbom, Å., 1988). Also discomfort is felt in other parts of the body - shoulders, arms, elbows, wrists, hand nerves and muscles or areas around these parts of the body.

In addition to the appearance of acute pain, there may also be the appearance of chronic pain in the mentioned parts of the body, and in some situations, permanent inability to work. According to the studies (Ohlsson, K., Attewell, R., & Skerfving, S., 1989) and (Ohlsson et al., 1995) conducted 39% of assembly workers in the automotive industry reported neck pain, 38% had shoulder pain, and 14% had arm pain. Luopajarvi, T., Kuorinka, I., Virolainen, M., & Holmberg, M. (1979) indicated that 37% of assembly workers complained of neck pain and 5.9% of arm pain.

Based on the above, it can be concluded that there is a need to improve traditional workstations in industrial environment. Good workstation design is crucial for industries that involve manual assembly activities by operators (Hägg, G. M., 2003). Monitoring the operator's muscle activity and identifying when fatigue occurs is of great importance, given that fatigue has a negative impact on the operator's health status (musculoskeletal disorders- back pain, carpal tunnel syndrome), productivity and operator's performance.

EMG as an electrophysiological method enables the registration of action potentials of muscle fibers of motor units that arise during muscle contraction. Using electromyography, muscle activities are monitored during the assembly of parts and components, and the load and strain on the muscles of the neck, arms and shoulders during these activities is determined.

The main aim of the research paper is to show the results of monitoring of muscle

activity during the performing of assembly activities in two scenarios - ergonomic and non-ergonomic in order to establish the risks that lead to the occurrence of musculoskeletal disorders and other occupational diseases among workers who perform assembly activities at traditional workstations.

The non-ergonomic scenario involves performing assembly activities at a traditional workstation in conditions that simulate conditions from a real industrial environment. On the other hand, in the ergonomic scenario, respondents perform assembly activities on the proposed new modular ergonomically designed workstation. In that case, the respondents perform assembly activities in the golden zone and in this way bending, stress and stretching of the body are eliminated.

Ergonomic interventions at the new workstation involve adjusting the height of the work surface, providing adjustable seating, and ensuring that tools and equipment are within easy reach.

This paper presented the results of monitoring the muscle of participants who perform assembly activities for a long period of time in an no ergonomic body position, in order to determine the ergonomic risks to the workers.

The motive for writing the paper lies in the fact that neglecting ergonomics in workstation design can indeed result in work-related musculoskeletal disorders and another occupational and work-related diseases. Poor workstation design can force workers to assume awkward postures, perform repetitive motions, or use excessive force, all of which can increase the risk of injury. For example, if the workstation is too high or too low, workers may have to hunch over or reach up, putting strain on their back, neck, and shoulders.

## 2. The experimental study

### 2.1. Literature review

Assembly workers occupational diseases and serious illnesses of workers, which can even lead to the disability of workers, which further leads to more and more absenteeism of workers from work, reduced productivity and increased costs. Neglecting ergonomic in workstation will result in workrelated musculoskeletal disorders. MSDs (including carpal tunnel syndrome, tendonitis, tennis elbow and back pain) are a particularly common problem among assembly workers, as their work often involves repetitive frequent motions, awkward postures, and forceful exertions (Choobineh, A., Lahmi, M., Shahnava, H., Khani Jazani, R., & Hosseini, M., 2004; Faucett, J., Garry, M., Nadler, D., & Ettare, D., 2002). These conditions can be painful and debilitating, making it difficult or impossible for workers to perform their duties and causing absenteeism.

According to the results of a Norwegian survey, the majority causes of MSD were: 65 % pain in the neck or shoulder region and 78 % arm pain (Mehlum, I. S., Veiersted, K. B., Wærsted, M., Wergeland, E., & Kjuus, H., 2009). Upper extremity disorders are a significant problem in assembly workplaces, both in terms of their commonness and the associated costs (Xu, Z., Ko, J., Cochran, D. J., & Jung, M. C., 2012). The costs associated with upper extremity disorders can be significant. Workers with these conditions may require time off from work for medical treatment or recovery, which can lead to reduced productivity and increased costs in organizations (“Ergonomics in the workplace”, 2019). In this context, many studies have proposed basic design rules or guidelines to ensure that assembly workers are able to work in safe and comfortable positions that minimize the risk of musculoskeletal disorders. These guidelines

typically focus on ergonomic workstation design, which involves designing workspaces that are tailored to the physical and cognitive abilities of workers.

EMG signals are used to monitor workers' muscle condition. According to (Graham, R. B., Agnew, M. J., & Stevenson, J. M., 2009; Lundberg, U. et al., 1999) the level of muscle activity varies depending on the complexity of the task performed and the position in which the worker performs the activities. According to (Sommerich, C. M., Joines, S. M., Hermans, V., & Moon, S. D., 2000) surface EMG (sEMG) is a very reliable and valid tool for measuring muscle activity in a industrial environment. Using this method, it is possible to determine the maximum lifting load, lifting height, and the number of repetitions that the workers are able to handle before experiencing fatigue, all for the purpose of avoiding overexertion (Freitas et al., 2019).

In studies (Bongers, P. M., Ijmker, S., Van den Heuvel, S., & Blatter, B. M., Griffiths, K. L., Mackey, M. G., & Adamson, B. J., 2007) surface EMG was applied to investigate the effects of workstation redesign on muscle strain in workers performing assembly activities and it was concluded that muscle strain in the upper extremities and shoulders, including the trapezius muscles, was significantly reduced after the redesign.

In a study (Björklund, M., Crenshaw, A. G., Djupsjöbacka, M., & Johansson, H., 2000) the effect of a repetitive low intensity task to fatigue on shoulder position sense was investigated. Molinari, F., Knaflitz, M., Bonato, P., & Actis, M. V. (2006) assessed the changed spectrum of the EMG signals when fatigue occurred during dynamic muscle contraction. Also, EMG electrodes were used in a specially designed laboratory experiment simulating roofing jobs to examine the effects of common risk factors based on lower back muscle activity and working frequency (Wang, D., Hu, B., Dai,

F., & Ning, X., 2015). The authors (Heydari, A., Nargol, A. V., Jones, A. P., Humphrey, A. R., & Greenough, C. G., 2010) conducted a large-scale study involving more than 100 workers (some with chronic pain symptoms and some not), testing the lumbar paraspinous muscles as a predictor of low back pain risk. Two years later, the research was conducted again on the same participants, and a subgroup of respondents with a higher risk of back pain was identified. In some scientific research papers, sEMG has been combined with observational assessments and self-assessments, in order to obtain a comprehensive picture of the extent to which muscle strain occurs in workers performing assembly activities.

## 2.2. Methodology

The traditional workstation where workers perform activities in a real industrial environment is fixed and not adapted to the individual anthropometric characteristics and capabilities of the operator. Also, workers in the industry most often perform assembly activities in a standing position for a long period of time, and this has a negative impact on their health conditions. In order to overcome the shortcomings of the traditional workstation, the authors proposed a new workstation that is aligned with ergonomic and lean principles and adapted to the individual characteristics and capabilities of the operator.

Studies (Corlett, E. N., & Eklund, J. A. E. 1983; Devereux, J. J., Vlachonikolis, I. G., & Buckle, P. W. , 2002) have shown that in an ergonomically designed workplace, the risk of musculoskeletal disorders is reduced, the safety and health of workers is improved, stress is reduced, and this further positively contributes to increasing the efficiency and productivity of operators. Authors (Choobineh, A., Lahmi, M., Shahnava, H., Khani Jazani, R., & Hosseini, M., 2004) concluded that the neglect of ergonomic

principles at the workstation leads to work injuries and musculoskeletal disorders. (Brito, M. F., Ramos, A. L., Carneiro, P., & Gonçalves, M. A., 2017) showed that when designing a workstation, special attention should be paid to ergonomic aspects.

Performing activities in the golden zone reduces stretching, bending, reaching for materials and parts, and eliminates poor posture, which further contributes to increased efficiency and reduced activity time (Heilala, J., & Voho, P., 2001; Yusuff, R. M., & Abdullah, N. S., 2016) pointed out the importance of adapting the workplace to the physical characteristics, requirements, abilities and skills of workers.

### 2.3. Case study

The experimental study was conducted in the period March 2022-March 2023 in the laboratory for ergonomics and collaborative robotics at the Faculty of Engineering, University of Kragujevac.

#### Participants

15 respondents participated in both scenarios. The subjects were undergraduate, master's and doctoral students at the Faculty of Engineering, University of Kragujevac, male gender, right-handed, aged between 18 and 30, who do not suffer from musculoskeletal disorders and have no serious back or spine problems. All participants voluntarily participated in the experiment and signed the consent that they allow the data to be used for further analysis. Before performing the experiment, the subjects were familiarized with the procedure and their basic data (age, year of birth, height and weight) were collected.

#### Equipment

The experiment was performed using an EMG device. The EMG device used for advanced measurements was MuscleBAN BE, produced by the company PLUXSignals from Portugal (slika 1.). This portable and wearable device measures electromyography and motion data, enabling a wide array of biomedical research and physiotherapy applications („Plux Biosignals, MuscleBAN BE Data Sheet“, 2021). As the main features of this device, we can state that it is light and small, so it can be worn without causing the test subjects any discomfort or interfering with their work during the experiments.

**Image 1.** The MuscleBAN BE device (The image of the rash („Plux Biosignals, MuscleBAN BE Data Sheet“, 2021))

The Bluetooth capability at up to 10 meters means that there is no need for wires, which would similarly impede the workers during the experiment and increase its complexity. The signal noise is 3 mV, giving us the margin of error, though the very large number of data points (over 5 million measurements) obtained during each session should greatly reduce the effects of statistical noise on results. The main device's characteristics, taken from its instruction manual, are presented in table 1. („Plux Biosignals, MuscleBAN BE Data Sheet“, 2021).

**Table 1.** The main device’s characteristics

Communication	Bluetooth Low Energy
Range:	up to ~10m (in line of sight)
On-board Sensors	1 EMG; 1 Triaxial Accelerometer ( $\pm 4g$ ); 1 Triaxial
ACC resolution	14-bit
MAG resolution	16-bit
EMG resolution	12-bit
EMG signal noise	3 $\mu$ V
Battery	155mA 3.7 LiPo rechargeable (enables up to 8h in continuous operation)
Medical grade charger	guarantees galvanic isolation
Size	28x70x12mm
Weight	25g

The device was then turned on and connected via Bluetooth to a computer with OpenSignals software and the subject was asked to perform some basic movements such as raising the hand in order to confirm that it was working as intended. When the subject was ready, the recording of data via OpenSignals was started and the session could begin. (Jonsson, 1988). Also, during the experiment both the traditional and the proposed new ergonomically designed workstation were used Trigno Research+ (Delsys, SAD) equipment used to record, measure and wirelessly transmit sEMG signals from the Trigno EMG sensor to the base station (Jonsson, B. G. et al., 1988). The equipment consists of a base station, an EMG sensor, a laptop on which the software is installed, which has the role of collecting, processing and analyzing the data. The main specifics are that the Trigno Avanti™ sensors support a low-noise, high-fidelity sensing circuit for detecting EMG signals when muscles contract from the surface of the skin. The maximum distance for successful data transmission between the sensor and the base was 10 meters. Trigno Avanti™ sensors were placed on the trapezius muscles on the subject's neck on the left and right side. Maximum muscle contraction was taken into account when placing the sensor itself. The recorded signals will be analyzed in real time using LabChart software. Figure 2. shows the

Trigno Research+ equipment used during the experiment - a box as a base station and EMG sensors

**Figure 2.** Trigno Research+ equipment

Also, as part of the research, an EEG cap with an amplifier was placed on the head of the subjects as part of a separate experiment that was conducted in order to monitor the brain activity of the subjects. In the experiment, 3 IP cameras were used, which had the role of monitoring the positions of the workers' bodies from three different positions - one camera was placed in front of the workers, and the remaining two cameras were on the left and right sides of the workers.

**Experiment scenario**

The experiment was conducted twice in two different scenarios - ergonomic and non-ergonomic. In both scenarios, the experiment consisted of two sessions lasting 1.5 hours (90 minutes) each, during which the respondents performed the activities of assembling electronic components according to predetermined rules. The participants assembled the finished product by inserting

blue wires from the container into a part made of plexiglas and closing the switch according to the diagram displayed on the monitor (in the ergonomic scenario) or according to paper instructions (in the non-ergonomic scenario). Participants in the experiment first received initial instructions, and after that, they performed assembly activities for 15 minutes in order to practice.

Between sessions, participants had a short break of 15 minutes. Thus, including the time necessary to prepare the experiment, set up the equipment and prepare the subject. The experiment in the ergonomic scenario and the non-ergonomic scenario were not performed on the same day.

In the non-ergonomic scenario, participants perform assembly work activities at a traditional workstation (Picture 3.). In this scenario, conditions from a real industrial environment were simulated i.e. 2D schematics and 3D images of the participants assembling the final product were displayed in paper format on a binder that was placed on a stand to the right of the subject. Additional difficulties encountered in this type of scenario are related to the constant turning of sheets of paper showing 2D schematics and 3D images after each completed product.

In the non-ergonomic scenario, the Plexiglas parts were located in a box next to a traditional assembly workstation so that subjects had to bend over to reach this part. The parts and components necessary to perform the assembly activities were placed outside the green zone and the subjects had to stretch their body to reach them. Also, the problem was that there were wires of various colors in the containers and not only the blue wires that were used during the experiment, which made it even more difficult for them to carry out the activity.

After finishing the part, the subjects bent down to drop the finished product into the box next to the table. In the non-economic

scenario participants were exposed to noise while performing activities.

**Picture 3.** Participant performs an experiment on a traditional assembly workstation

The experiment in an ergonomic scenario was realized on a proposed innovative modular assembly workstation, which is designed in accordance with the lean principles, main ergonomics principles and adapted to the needs and requirements and individual characteristics of the operator (Picture 4.). Anthropometric properties and measurements are essential factors to consider when designing a new workstation. Anthropometry is the scientific study of the measurements and proportions of the human body, and it plays a critical role in designing workstations that are ergonomic and safe for workers (Wojcikiewics, 2003). In order to design a workstation that is suitable for at least 90 percent of male and female body sizes, designers must take into account a variety of anthropometric factors, such as body height, weight, arm length, and leg length.

At the new workstation, the subjects had the possibility to adjust the height of the table and chair to match their height, and the control zone was adjusted to the individual reach of the dominant hand and individual preferences. In new assembly workstation all

components storage containers are arranged taking into account that the zones of the handling area are different for each person to reduce bending, straining and stretching of the body. The flexible arrangement of containers for storing parts and components on the newly designed workstation provides the ability to change the layout and organization of the work environment and adapt to the individual reach of the examinee. At the proposed assembly workstation, respondents perform activities in a combined (sitting and standing position) without feeling tired, exhausted and physically strained.

In the ergonomic scenario, the participants performed assembly activities based on information about 2D schemes and 3D images that they received from the touchscreen screen in front of them. Also, in the ergonomic scenario, the Plexiglas parts were placed on the right side of the subject within the golden zone to avoid unnecessary bending of the body. The container with the blue wires used during the experiment was placed in accordance with lean and ergonomic principles to avoid unnecessary reaching and stretching of the body. The experiment was performed in a ideally laboratory conditions.

**Picture 4.** Participant performs an experiment on a proposed modular assembly workstation

Using innovative EMG technologies, muscle activity was measured in real time during both scenarios individually. Before placing the MuscleBAN device, the skin around the subject's upper trapezius muscles was first cleaned and disinfected, and then a gel for isotonic recording electrodes was applied to it. During the experiment GEL101A electrode paste was used, which is specially formulated with 0.5% saline added to a neutral base to create an isotonic, 0.05 molar NaCl, electrode paste. Unlike agar or saline pastes, this paste has a virtually unlimited shelf life, making it suitable and efficient to use in long-running experiments (ELECTRODE GEL, ISOTONIC, n.d.). After the gel has been applied and any excesses of it removed, the MuscleBAN BE EMG device was placed and secured via strong tape to both sides of the trapezial muscles.

### 3. Results and discussion

Figures 5. and 6. show the raw signals of monitoring muscle activity on the left and right hand of one subject using the MuscleBAN BE device and Trigno Research+ equipment

**Figure 5.** Raw sEMG signal using the MuscleBAN BE device in non-ergonomic scenario (left hand)

**Figure 6.** Raw sEMG signal using the MuscleBAN BE device in non-ergonomic scenario (right hand)

**Figure 10.** Raw sEMG signal using the Trigno Research+ equipment in non-ergonomic scenario (right hand)

**Figure 7.** Raw sEMG signal using the MuscleBAN BE device in ergonomic scenario (left hand)

**Figure 8.** sRaw EMG signal using the MuscleBAN BE device in ergonomic scenario (right hand)

**Figure 9.** Raw sEMG signal using the Trigno Research+ equipment in non-ergonomic scenario (left hand)

Raw s EMG signals are the basis for conducting time analysis, frequency analysis and feature analysis in the following period.

## 4. Conclusion

In the context of Industry 4.0, a human-centered workplace is one that incorporates advanced technologies and digital systems in a way that supports workers and enhances their capabilities, rather than replacing them or making their jobs more difficult. By leveraging the power of new technologies, organizations can improve their occupational safety and health practices and create safer and more pleasant workplaces.

Workers who perform repetitive and tedious activities at a traditional assembly workstation for long periods of time are at risk of developing musculoskeletal disorders, such as carpal tunnel syndrome, tendinitis, and back pain. These conditions can cause physical discomfort and pain for workers, and can lead to reduced productivity, absenteeism, and even long-term disability.

Monitoring muscle activity and implementing preventive activities in order to reduce the occurrence of musculoskeletal disorders and other occupational diseases to which workers who perform assembly activities are exposed is very important. Using EMG equipment, the electrical activity of muscles during contraction and relaxation was measured for assessing the load and strain on the muscles. By analyzing

the EMG signals, it can be determined whether the muscles are being overloaded or strained.

The directions of future research are related to the detailed analysis of data obtained by monitoring muscle activity in real time in order to and observation assembly activities by video-camera in order to optimize the worker's body posture and avoid uncomfortable or unsafe postures and to

improve health and safety of workers who perform repetitive, tiring and monotonous assembly activities for a long period of time in an unergonomic position. In this way, the risk of musculoskeletal disorders will be reduced and the overall performance of the system will be improved. The results will be compared with the results obtained using the ergonomic methods RULA and REBA.

## INDUSTRY 4.0 AND INDUSTRY 5.0 – OPPORTUNITIES AND THREATS

**Abstract:** *Industry 4.0, also known as the fourth industrial revolution, is a concept that refers to the application of high technologies, such as the Internet of things (IoT), cybernetics, machine learning, and automation, in production and business processes. One of the main goals of Industry 4.0 is to create "smart factories" that can adapt to changing market conditions and customer needs and increase efficiency and productivity through advanced technologies. This is achieved by connecting machines, devices, and systems to the internet, allowing them to communicate and share data in real-time. This enables the factory to be more responsive to demand changes and optimize production processes. Industry 4.0 also has the potential to change the way we work and interact with machines, through the use of advanced technologies such as augmented reality and human-machine interfaces. This can lead to more flexible and efficient work processes and create new opportunities for workers to develop new skills.*

**Keywords:** *Industry 4.0; Industry 5.0; Challenges; Smart factory; Human-centric*

### 1. Introduction

Staying at the top is becoming increasingly difficult and challenging due to rapidly growing and variable digital technologies and artificial intelligence-based solutions. The world of technology, mass customization, and advanced production is undergoing a rapid transformation. Robots are becoming even more important as they can now be connected to the human mind through brain-machine interfaces and advances in artificial intelligence. Digitalization has created a new paradigm in production, where factories are becoming more modern and sophisticated. Although the manufacturing industry aims to establish nearly fully automated factories in order to achieve savings, it has raised concerns about the elimination of human jobs.

In 2011, the German government created the term Industry 4.0 to describe the increasing trend of automation and data exchange in manufacturing technologies (Lu, 2018). This term is widely used by the European Commission and the EU government to direct policy towards the development of innovation and digitization of European, namely small and medium-sized enterprises (SMEs) (Probst et al., 2018). Implementing Industry 4.0 requires significant transformations throughout the organization (Schneider, 2018; Sony & Naik, 2020). New technologies also require new workforce competencies (Pejic-Bach et al., 2020). Industry 4.0 brings a new concept of business, the so-called "smart factory" concept.

Smart factories operate as smart systems that rely on the ability to exchange information about inventory status, and order changes,

Email: [jovana.nikolic.jag@gmail.com](mailto:jovana.nikolic.jag@gmail.com)

aiming to achieve decentralized coordination between the processes themselves (Castelo-Branco et al., 2022). These types of factories increase business productivity, therefore, Industry 4.0 has certain limitations - the lack of collaboration between humans and machines.

Industry 5.0 changes the paradigm and provides a solution by reducing the focus on technology and emphasising the potential for progress based on collaboration between humans and machines. In modern business with continuous technological advancements, Industry 5.0 is necessary for gaining competitive advantages and economic growth for organizations. The concept of Industry 5.0 was introduced in 2015 and has the greatest impact on production automation, using artificial intelligence (AI) to improve production process performance. This revolution aims to shape and transform business activities through the use of smart tools (Halim & Javaid, 2019), to put the well-being of people at the centre of production systems and provide the opportunity for sustainable development for all of humanity (Leng et al., 2022).

Overall, current literature and research on Industry 5.0 are relatively scarce, and the industry is still emerging. This paper aims to analyze the potential applications of Industry 4.0 and 5.0 and the concept of human-machine collaboration.

## 2. Literature review

The new industrial revolution called Industry 4.0 encompasses almost all areas of industry and science in the context of automation and reducing the need for human labour (Buntak et al., 2021), which in some business systems, such as logistics, can significantly reduce costs and increase efficiency. However, parallel to the development of technological innovations within Industry 4.0 such as the Internet of Things, Digital

Twins, Big Data, artificial intelligence etc, a challenge arises related to data security (Kovačić et al., 2022) since these technologies function based on sharing data between different machines and devices, and access to such data by third parties can result in the risk of taking control and potential damage. Nonetheless, despite the described risk, according to (Flores et al., 2020), the emergence of new technologies and new risks related to new technologies also leads to the need to change the existing competencies of human resources, which require new knowledge based on managing new technologies, rather than simply executing tasks, which is a result of automation and reduced need for the workforce. Damayanti's research conducted in 2021 supports these conclusions: Speaking specifically about the new competencies required by employees, it is important to emphasize that these competencies are primarily related to increasing IT skills, primarily programming and maintenance of such technologies in the context of replacement and repairs, as emphasized by (Alhloul & Kiss, 2022). However, since the use of automated systems exclusively means the potential risk of reduced need for human labour, there is a significant risk of a lack of social responsibility, primarily towards the social component. Nevertheless, it should be emphasized that, from a system management perspective, the significant use of automated systems can contribute to increasing the organization's competitiveness and the ability to personalize products that customers demand from the organization, as written by (Saniuk et al., 2020).

The challenges described are becoming the basis for a new industrial revolution called Industry 5.0, which is based on collaboration between humans and automated systems (Xu et al., 2021). In other words, the concept of exclusive automation is being abandoned and a shift is being made towards

reintroducing humans as the centre of the process, with automated systems no longer operating independently but serving as an aid to humans, which significantly improves the quality of work performed as described by (Nahavandi, 2019). This reintroduces the creative component into the process, which has been significantly neglected until now since automated systems have not had the ability for creative thinking, as creative thinking is currently exclusively a human characteristic (Leng et al., 2022).

On the other hand, as stated in the research (Basten et al., 2020), increasing the competitiveness of organizations through the implementation of new technologies can lead to a widening gap between employees who possess the necessary knowledge and skills to work in Industry 4.0 and those who do not. Therefore, to reduce this gap, it is necessary to invest in education and workforce development to create qualified experts for Industry 4.0, as emphasized in the research (Ceric & Kascelan, 2020).

In conclusion, Industry 4.0 refers to the trend of automation and data exchange in manufacturing, which has great potential for reducing costs and increasing efficiency but also poses challenges in terms of data security. The application of new technologies also requires the development of new competencies for employees, as well as investment in education and workforce development to reduce the gap in skills and knowledge needed for work in Industry 4.0.

Besides, speaking in general terms, Industry 5.0 represents a continuation of Industry 4.0 and the technologies that were characteristic of Industry 4.0 is still being used, with the difference being that they are now being utilized by humans (Maddikunta et al., 2022). Nevertheless, one of the technologies that stand out, in particular, is artificial intelligence since it enables the analysis and execution of a large number of activities in a very short time with human instructions. This approach significantly impacts the

ability to collect and analyze large amounts of data in a short period, which is the basis for making decisions about future actions as discussed by (Stone et al., 2020). However, since Industry 5.0 is still in its early stages and some countries have not fully utilized the potential offered by Industry 4.0, it is expected that the full potential of Industry 5.0 technologies will only be seen in the future, according to (Leng et al., 2022).

### 3. Industrial revolution

Looking back to 1780, the first industrial revolution (Industry 1.0) was born with the generation of mechanical energy from water, steam, and fossil fuels (Nahavandi, 2019). The next shift towards the manufacturing industry between 1871 and 1914 was called Industry 2.0, which enabled a faster transfer of people and innovative ideas. This revolution was a period of economic growth and increased business productivity, which also led to rising unemployment as machines replaced factory workers (Amr, 2022). Almost a century later, in the 1970s, industrialists began to use electronics and computers in manufacturing. The Third industrial revolution (Industry 3.0) utilized microprocessors, information technology, and robots for high-level automation in production. Soon after, there was an increase in globalization and outsourcing of production due to the availability of skilled labour and lower production costs. Industry 4.0 means the integration of intelligent machines and systems and bringing changes to production processes to increase manufacturing efficiency. Industry 4.0 refers to resilient technology, new ways of working, and the role of people in the industry. Industry 4.0 brings about a wide range of innovations in the operations and factories of different industries and services, affecting the functioning of entire societies. At its core, it represents a trend towards automation and data sharing in production

technologies and processes, utilizing cyber-physical systems, the Internet of Things, cloud computing, cognitive computing, and

artificial intelligence (Grabowska et al., 2021).

**Figure 1.** From Industry 1.0 to Industry 5.0 (Autor)

Industry 5.0 is an emerging technology that advances the design of the previous generation, with a focus on efficient and intelligent machines. The concept of Industry 5.0 was deliberated among participants from research and technology organizations at the Directorate "Prosperity" of the European Commission's DG for Research and Innovation from July 2 to July 9, 2020. The EC document presents assumptions about the concept of Industry 5.0, emphasizing the critical directions for change to achieve a more sustainable and human-centred industry (Breque et al., 2021). As a new and enhanced version of Industry 4.0, Industry 5.0 is being promoted as a model that will bring further prosperity and competitiveness to businesses while promoting a human-centric economic model.

#### 4. Distinguishing Industry 4.0 from Industry 5.0

In today's world, people work alongside machines and are connected to smart factories through intelligent devices. The world of technology, mass customization, and advanced manufacturing is going through a rapid transformation. Robots are becoming even more important because they can now be connected to the human mind through brain-machine interfaces and advancements in artificial intelligence. Today, robots are intertwined with the human brain and work as collaborators, not competitors. The Industry 5.0 revolution will likely stimulate more advanced human-machine interfaces using artificial intelligence algorithms (Grabowska et al., 2021). Industry 4.0 and Industry 5.0 refer to the integration of advanced technologies into the manufacturing process, but there are some key differences between them.

Industry 4.0 refers to the current trend of automation and data exchange in manufacturing technologies. It includes developments such as the Internet of Things (IoT), artificial intelligence (AI), and machine learning (ML). The aim of Industry 4.0 is to create "smart factories" that can adapt to changing market conditions and customer needs and increase efficiency and productivity by using advanced technologies.

Industry 5.0 is built on the foundations of Industry 4.0 but takes it to a higher level by integrating even more advanced technologies such as quantum computing, 5G networks, and blockchain. The goal of Industry 5.0 is to create an even more flexible, efficient, and sustainable production process. By bringing human workers back to the factory floor, Industry 5.0 will pair humans and machines to further leverage the human brain and creativity to increase process efficiency by combining workflows with intelligent systems. While Industry 4.0's primary focus is on automation, Industry 5.0 will be characterized by a harmonious integration between humans and autonomous machines. The autonomous workforce will possess the ability to perceive and understand human intentions and desires. Humans and robots will work together as collaborators, without fear, but with a sense of ease, knowing that their robotic counterparts can comprehend and effectively cooperate with them. While Industry 4.0 focuses on automation as its main concern, Industry 5.0 will be a symbiosis between humans and autonomous machines. The autonomous workforce will be perceptive and informed about human intentions and desires. The human race will work together with robots not only without fear but also peacefully, knowing that their robotic collaborators understand them adequately and have the ability to effectively cooperate with them. This will result in an extremely efficient production process with added value, thriving reliable autonomy and reduced waste and associated costs. Industry

5.0 will redefine the word "robot" as not just a programmable machine capable of performing repetitive tasks, but as an ideal human companion for certain scenarios. Cobots, the next generation of robots, will already know or quickly learn what to do and will be aware of human presence, taking into account safety and risk criteria. They can perceive, understand and sense not only the human being but also the goals and expectations of the human operator. Like an apprentice, cobots will watch and learn how an individual performs a task and when they learn, they will perform the desired tasks like their human operators. Therefore, humans experience a different sense of satisfaction while working together with cobots (Nahavadi, 2019).

Contrary to the depiction of the future in science fiction movies, digitization will not render human workers in industrial production obsolete. Instead, it will integrate intelligent automation, devices, and systems in the workplace to enhance collaboration between humans and machines. This will allow highly skilled workers to lead smart machines and robots and work more efficiently alongside cobots.

Industry 5.0 would solve the need for personalization and mass customization of products for customers. This would stimulate and apply human intelligence and thought processes in computers - a process known as cognitive computing. Robots and automation are playing an increasingly important role in modern factories. Smart factory cobots would also be smart enough to understand the needs of the human operator, decide if they need assistance, and assist them accordingly. Cobots (robots designed to work alongside humans) can assist the human factor in factories in various ways, including:

**Improving safety:** Cobots can take on tasks that are dangerous or too strenuous for humans. For example, cobots can lift heavy objects, perform hazardous tasks in

dangerous environments (such as in mines or on oil rigs), or work in conditions with high temperatures or high levels of pollution.

**Improvement of product quality:** Cobots can be programmed to perform tasks with a high degree of precision, reducing the likelihood of errors and increasing product quality.

**Increased flexibility:** Cobots can be quickly reprogrammed to work on different tasks, making the production process more flexible and adaptable.

**Improving employee satisfaction:** Cobots can take over tasks that are uninteresting for humans, allowing them to focus on more creative and challenging tasks. This can lead to increased employee satisfaction and reduced stress.

**Cost reduction:** Although the initial investment in purchasing and implementing robotic equipment is high, the use of robotic technology can lead to long-term cost savings. Cobots can reduce labour costs, reduce material losses, and increase production process efficiency.

To better utilize human creativity and brainpower and improve operational efficiency, I would combine intelligent systems with existing workflows. This would shift the focus in factories away from mass production, automation, and digitization, which were the key elements of Industry 4.0. In summary, cobots can aid the human factor in factories in numerous ways by increasing efficiency, safety, and product quality. This will lead to better integration, allowing for faster and better automation in combination with the power of the human brain. It also means that robots will not take over control of production plants shortly, as previously feared in the era of Industry 4.0.

In conclusion, Industry 5.0 represents a more advanced and holistic approach to production, aiming not only to increase efficiency and productivity but also sustainability and a human-centric approach. This involves combining the best of both

worlds - human and machine - to increase productivity (Grabowska et al, 2021).

#### **4.1. The concept of people and machines**

Industry 4.0 is based on the concept of smart factories. Smart factories are factories equipped with modern technology and systems that enable high automation and optimization of production processes. The following key drivers can be identified:

- **Internet of Things (IoT):** IoT enables the connection of different devices, sensors, and machines into a unified system and the exchange of data between them. This enables a high level of automation as well as real-time monitoring of machine performance and maintenance.
- **Artificial Intelligence (AI):** AI enables machines to learn and improve their performance over time based on the analysis of large amounts of data. AI can be used for optimizing production processes, reducing material losses, monitoring and predicting failures, and other purposes.
- **Robotics:** Robotics is crucial for the automation of production processes. Robots can be used for various tasks, including lifting and moving heavy objects, assembling products, inspecting quality, and other tasks typically performed manually.
- **Cloud technologies:** Cloud technologies enable the storage and processing of large amounts of data remotely. This allows for real-time monitoring of machine performance as well as data analysis to improve efficiency and reduce costs.
- **Advanced sensors:** Advanced sensors enable the measurement of various parameters in real-time, including temperature, humidity, pressure, speed, and other

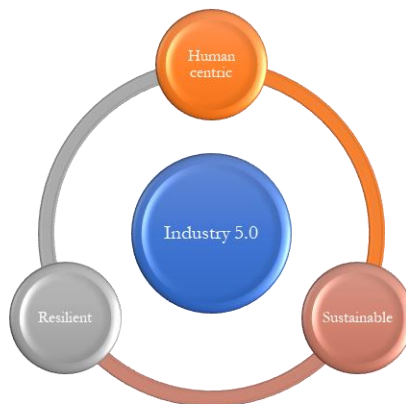

parameters. This enables monitoring of performance and prediction of failures before they occur.

- Digital simulation: Digital simulation allows for testing and optimization of manufacturing processes before they are implemented in practice. This can help reduce costs and increase production efficiency.

Industry 5.0 is characterized by its focus on sustainability, which means it's not only

concerned with increasing efficiency and productivity, but also with reducing the impact of production on the environment, utilizing more renewable energy sources, and promoting a circular economy. These technologies enable high automation and optimization of production processes, resulting in increased efficiency, cost reduction, and improved product quality.

Three fundamental principles of Industry 5.0. (Figure2) are human-centricity, sustainability, and resilience(Gonçalves, 2022):

**Figure 2.** Industry 5.0 with tree key drives (Zizic et al., 2022)

One empty single line should be left before table and after it's title. Table headings should be placed above the table, as shown in this template. The width of all lines in tables including all borders should be 1/2 pt. Text and numbers in tables should be typewritten in Times New Roman, 9 pt.

Figures and tables should not be placed at the end of the current section. It is recommended that footnotes be avoided. Instead, try to integrate the footnote information into the text.

Human centricity is one of the key principles of Industry 5.0, which places people and their needs at the centre of the manufacturing process. This approach recognizes that

technology should serve people and society and emphasizes the importance of adapting technology to meet the needs of workers, rather than forcing workers to adapt to technology. Manufacturers must recognize the potential of technology to enhance the work environment, while also addressing concerns around autonomy and privacy (Amr, 2022).

Sustainability is one of the three fundamental principles of Industry 5.0, which aims to use resources that meet the current needs of the manufacturing industry. The collaboration between humans and machines promotes flexible business models and reducing waste and overproduction is essential. The

promotion of local production can help to make the economy more sustainable. Industry 5.0 fosters the development of sustainable policies, such as minimal waste creation and efficient management, using corporate technologies. It emphasizes creative research and knowledge to drive innovation and evolution.

The principle of resilience is one of the three pillars of Industry 5.0, which emphasizes the need to enhance the robustness of production and supply chains. This makes them more resistant to disruptions and able to secure and support critical infrastructure during crises. This principle complements the sustainability principle. As environmental shocks become more prevalent, companies will need to be flexible enough to handle the unforeseen consequences of unpredictable weather conditions.

#### **4.2. Benefits of implementing Industry 5.0.**

Industry 5.0 represents a new paradigm of industrial production that involves collaboration between humans and machines to create highly customized and personalized products. Although this paradigm is still in its infancy, there are some predictions about its development and use in the future:

- **Increased production flexibility:** Industry 5.0 enables the production of personalized products in smaller batches, which increases the flexibility of the production process. This should lead to a reduction in product storage and transportation costs, as well as a reduction in waste.
- **Increased efficiency:** Integration of digital and physical systems allows for the optimization of production processes and reduces unnecessary energy consumption. This should lead to a reduction in production costs and an increase in efficiency.

- **Increased collaboration between humans and machines:** Industry 5.0 enables real-time collaboration between humans and machines, which should lead to increased productivity and reduced errors.
- **Reduced need for physical labour:** The introduction of automation and robotics in production reduces the need for physical labour. This could lead to increased productivity and reduced costs.
- **Potential for new types of business:** Industry 5.0 enables the creation of new types of businesses, such as personalized products and services, which could lead to economic growth and the creation of new jobs.

Industry 5.0 is expected to introduce a new position in the production process: Chief Robotics Officer (CRO). The CRO will be a specialist in robotics and the interaction between robots and humans. Their role will be to make decisions about adding or removing machines or robots from the factory floor in order to optimize performance and efficiency. The CRO will have expertise in robotics, artificial intelligence, human factors modelling, and human-machine interaction. With access to collaborative robotic technologies and leveraging advancements in computing, the CRO will be well-positioned to positively impact environmental management. This will ultimately lead to increased sustainability by reducing pollution and waste and preserving the planet.

Contrary to the assumption that people will lose their jobs due to artificial intelligence, many studies have shown different results. It is estimated that future technologies will contribute to expanding the global production workforce by up to 4% by 2030, from the current 1.2 billion people (McKinsey Global Institute, 2017). Supply chain management in all industries would

also become more agile and innovative due to increased investment in research and development, intelligent sales and marketing, distribution, and value-based pricing.

However, it should be noted that Industry 5.0 is still evolving and it is difficult to accurately predict its future benefits and challenges

## 5. Conclusion

Based on the analysis presented in this paper, it can be concluded that in Industry 4.0, companies worldwide are automating their production setups and connecting smart devices to enable digital communication between them. This has allowed machines to perform repetitive and laborious tasks. The upcoming Industry 5.0 will focus on bridging the gap between robots and highly skilled human workers to produce and deliver the best individual products, services, and customer experiences. Here, human intervention would be more intellectual than physical.

Industry 5.0 will bring unprecedented challenges in the field of human-machine interaction, as machines will be brought very close to the everyday life of every person. Moreover, it is expected that Industry 5.0 will open up many job opportunities in the field of human-machine interaction and computer analysis of human factors.

Industry 5.0 will revolutionize production systems worldwide by taking away "boring", dirty, and repetitive tasks from the human

workforce wherever possible. Intelligent robots and systems will penetrate supply chains and manufacturing facilities to an unprecedented level. This will be enabled by the introduction of cheaper and highly capable robots made of advanced materials such as carbon fibre and lightweight yet strong materials, supported by highly optimized batteries, reinforced with cyber attacks, with stronger data handling processes (data and artificial intelligence) and networks of intelligent sensors. Industry 5.0 will increase productivity and operational efficiency, be environmentally friendly, reduce workplace injuries, and shorten production cycles. However, contrary to the desire for digitalization and automation of work processes, Industry 5.0 will create surplus jobs. A large number of new jobs will be opened up in the field of intelligent systems, artificial intelligence and robotic programming, maintenance, discovering new types of robots for production, etc. In addition to all the above, tasks that are currently being repeated in certain processes will no longer need to be performed by humans in the future. This will enable creativity to be encouraged in the work process, encouraging everyone to innovatively use different forms of robots in the workplace. However, as a direct impact of Industry 5.0, a large number of start-up companies will build a new ecosystem of providing customized robotic solutions, in terms of hardware and software, worldwide. All of this will further stimulate the global economy and increase the inflow of money worldwide.

## **ADVANTAGES AND DISADVANTAGES OF TECHNIQUES AND PROCESSES OF 3D PRINTING IN INDUSTRIAL APPLICATION**

***Abstract:** The fourth industrial revolution is underway, which places the greatest emphasis on the digitization of processes in production and services. Technology is developing more and more every day, and so is its influence in production activities and industrial applications. The focus is on innovative technologies, including 3D printing. Industry 4.0 is closely related to sustainable production, as it optimizes energy and resources. Smart factories are being created, which operate in accordance with the postulates of energy efficiency, better competitive advantages in the conditions of global business, in a virtual business environment, where additive manufacturing is included. The aim of this paper is, in summary, to examine the impact that 3D printing has in production, in the context of advantages and disadvantages of techniques and processes in industrial application.*

***Keywords:** 3D printing, Industry 4.0, Sustainable production, Advantages and disadvantages*

### **1. Introduction**

Industry 4.0 is considered a new driver of industrial development and the fourth industrial revolution, an upgrade of the previous three (Iivari et al., 2020). It is seen as an advanced manufacturing model that is represented by intelligent, virtual and digital performance in large industries. The new industrial model itself includes an integrated structure throughout the factory and potential technologies in various areas of industrial activity, and these technologies are in line with the principles of Industry 4.0 design, which are also responsible for ensuring the innovative performance of this new industry. Sustainable industrial production within Industry 4.0 can be seen in the context of creating smart factories and accompanying processes: energy efficiency, waste reduction, employee safety, increased job opportunities, smart production, virtual

processes, extended value network, additive manufacturing, etc. In these conditions, 3D printing or additive manufacturing finds its great application in various industries. Companies around the world are increasingly oriented towards smarter, digital production, and the relevance of industrial 3D printing is primarily reflected in the reduction of operating costs and shorter production time (Hao et al., 2020).

### **2. Industry 4.0**

The history of the industry since its inception has been marked by great changes, the acquisition of great knowledge, events and discoveries that changed the structure of cities, their populations, the types of products they offer and the way they offer them, innovations in the development of production processes and the way employees work, between many other aspects. It can be

---

verified as a result of the combination of three fundamental aspects: knowledge, experimentation and entrepreneurial innovation (Ramya et al., 2016). These aspects have effectively contributed to the development of new products and services. Industry has its evolution distributed in different stages of equal importance, from the first to the fourth revolution. Industry 4.0 fully utilizes all the foundations of the previous industrial revolutions, but with higher rates of integration, digitization, virtualization, technologies and fast times, we see that the industry has undergone many changes and improvements in each of its phases, products have evolved, ways have changed distribution, customer requirements, people work, internal and external aspects. Knowledge of Industry 4.0 and all its possibilities in different areas is essential to fully exploit its potential, and also for those who want to realize a form of cooperation in the new industry. It is important that they know all the new possibilities it presents. Some of the technologies of Industry 4.0 that have the greatest impact in the framework of the production planning process and the realization of production activities, according to the aforementioned claims, would be (Hamilton, 2020, Wu, 2016):

- Cloud Computing,
- Big Data,
- Digital Twin,
- 3D printing,
- Artificial intelligence.

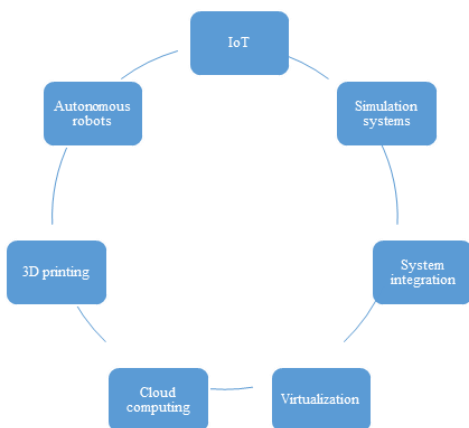

## **2.1. Sustainable manufacturing in industry 4.0**

We are witnessing the accelerated digitization and transformation of business processes in the conditions of globalization. New forms of business are being developed, largely based on and guided by the postulates of preserving the environment, energy and natural resources. Sustainable production becomes imperative. It

encompasses the methodology of green production and also adds other dimensions to it. Sustainable production focuses on the entire life cycle of a product, starting from the manufacturing process to its "end of life", followed by remanufacturing and recycling (Arena et al., 2009, Miśkiewicz et al., 2020).

Sustainable manufacturing is viewed from different dimensions depending on its purpose and application; however, widely accepted dimensions among industry participants are environment, society, economy, technology and performance management. Of the mentioned dimensions, environment, society and economy are considered as the "three pillars" of sustainable development and are often known as the "triple bottom line". The main goal of sustainability could be seen in the context of designing and developing production processes and products, where there is no impact on the environment and 100% product recycling is achieved. On the one hand, technological progress enables the development of processes and products to achieve sustainable development, while digital technologies must be in cohesion with sustainability. Industry experts and researchers use Industry 4.0 technologies to understand all the challenges and details related to sustainable production. It is believed that environmental challenges such as climate change, resource depletion and environmental protection will be solved by Industry 4.0 technologies. This creates a new perspective for Industry 4.0, which has traditionally been about digitizing operations and reaping benefits. However, for this to happen, there should be complete coherence and convergence of Industry 4.0 technologies. Figure 1 shows the important technological drivers of the fourth industrial revolution, which is expected to play a significant role in achieving sustainable manufacturing of the future (Novikova, et al., 2012, Rojko, 2017).

The transformation of a production unit into an intelligent factory requires both horizontal and vertical integration, whereby all production participants are integrated. Seamless integration, provided by Industry 4.0 technologies and information and communication technology platforms, increases the transparency of production processes and supply chain activities, thus helping to optimize all energy and resources. Such connected operations produce vast amounts of data related to every aspect of production. When all such data are transformed into useful information, they will play a key role in the development of strategies from an environmental, social and economic perspective (Miśkiewicz et al., 2020).

**Figure 1.** Industry 4.0 and sustainable manufacturing

Regarding the environmental dimension of sustainable production, Industry 4.0 helps reduce waste generation through its simplified production process and efficient recycling and remanufacturing initiatives. For example, transparency in any production operation or process is significantly increased by incorporating different types of sensors. Such sensors also provide valuable information including behavior, usage, failure models, performance indicators,

emissions, performance under critical conditions, etc., of the product during its life cycle. Such information is used to develop better products and processes using various simulation systems, to mitigate negative impacts on the environment, without impairing its competitiveness. Such integrated systems also help in monitoring and managing the losses incurred in the life cycle of the product, both in the production phase and in use. Therefore, with full transparency, manufacturers can design new products that are more competitive and environmentally friendly, achieving sustainability (Melnik, 2018).

From an economic point of view, Industry 4.0 with the help of the Internet of Things, artificial intelligence, machine learning, machine vision and data analytics, enables the development of equipment at much lower costs through efficient use of energy and resources. Manufacturers are continuously exploring ways to reduce their operating costs involved in manufacturing activities. However, challenges such as waste generation (arising from production and maintenance activities), reduced productivity and increased energy consumption threaten the strategies that manufacturers have developed to reduce costs. With proper implementation of Industry 4.0 technologies, manufacturers will be able to see optimized and non-optimized processes in their value chain. In addition, strategies such as the use of new and cleaner manufacturing technologies and the use of 3D printing will also help manufacturers reduce waste generation (Ngo et al., 2018).

Regarding the social dimension of sustainable production, Industry 4.0 helps develop better products, which in turn benefits society as a whole. In addition, many better jobs will be created. Industry 4.0 technologies are expected to play a significant role in driving sustainability in industrial production. However, it is still too

early to talk about aligning technologies with sustainable development goals. To realize this, manufacturers need to transform their factory into an intelligent factory with full horizontal and vertical integration. Manufacturers want to understand the benefits of Industry 4.0 to transform themselves into a smart factory aligned with sustainable goals (Miśkiewicz et al., 2020).

### 3. 3D printing in manufacturing

3D printing in manufacturing has experienced a major expansion in recent years, which continues to this day. In addition to this name, it is often associated with the term additive manufacturing. For almost 40 years, this technology has been on its development path - from the technology that was originally used for prototyping to today's use in various industries (Gao et al., 2015). We have witnessed the use of this

technology in a large number of companies around the world, on a different or similar scale. Uses can be related to utility tools, visual and functional prototypes, or even end-use parts. Common types of 3D printing technology include SLA (stereolithography) three-dimensional engraving technology; FDM (Fused Deposition Modeling) selective coating of filamentous material; SLS (Selected Laser Sintering) selective sintering of powder materials; production of laminated objects; Selective powder bonding technology for 3D printing etc. (Gibson et al., 2015, González-Henriquez et al., 2022, Hao et al., 2020)). As the potential applications for 3D printing increase, companies are beginning to find ways to create new business models and opportunities with said technology. Thus, 4D printing is already under development (Figure 2) (Mahmood et al., 2022).

**Figure 2.** The evolution of printing to 4D printing that adds a time dimension (Mahmood, 2022)

The basic specification is that the 3D printer moves in three dimensions to form 3D structures. The term 4D printing refers to the addition of a fourth dimension, time, which essentially means that these 3D printed objects transform and change shape over time under the influence of external stimuli such as water, light, heat, pH, electricity, magnetic fields, and so on. The resulting object would be called a 4D printed object that was printed with a 3D printer, but using 4D printing materials. Accordingly, 4D

printing material is essentially a material that can transform or change its shape over time when exposed to external stimuli (Ryan et al., 2021).

One of the first industries to recognize the potential of 3D printing is the aerospace industry, as well as the defense industry. Thus, the importance is reflected in research projects, but also in real applications, such as: functional prototypes, tools, light components. 3D printing in the aerospace industry is not limited to prototypes. Real,

functional parts are also 3D printed and used in airplanes. A few examples of parts that can be produced using 3D printing include air ducts (SLS), wall panels (FDM), and structural metal components. The advantages of 3D printing within these industries are reflected primarily in the satisfaction of low-volume production, where highly complex parts are produced in small quantities. Using technology, complex geometries can be created without investing in expensive equipment and tools. This provides OEMs and suppliers with a cost-effective way to produce small batches of parts in a cost-effective manner. Reducing the weight of an aircraft can significantly reduce its carbon dioxide emissions, fuel consumption and payload (Joshi et al., 2015, Mallakpour et al., 2021).

Because the 3D printing process works by producing parts layer by layer, the material is generally only used where needed. As a result, it produces less waste than traditional methods. The range of materials available for 3D printing is constantly increasing, creating advanced applications in aerospace. One of the key benefits of 3D printing is part consolidation: the ability to integrate multiple parts into a single component. Reducing the number of required parts can significantly simplify the assembly and maintenance process by reducing the time required for assembly. The average lifespan of an aircraft can range between 20 and 30 years, making maintenance, repair and overhaul an important function in the industry. Metal 3D printing technologies such as direct energy deposition are commonly used to repair aerospace and military equipment. Turbine blades and other top equipment can also be renewed and repaired by adding material to the worn surfaces. 3D printing, especially of metals, is increasingly being used in rocket production. The technology allows engineers to innovate the design of rocket parts and produce them in a shorter time frame. The injector head is

one of the basic elements of the power module, which pushes the fuel mixture into the combustion chamber. Traditionally, injector heads are made from dozens or even hundreds of parts, which need to be machined and welded together. 3D printing allows these components to be manufactured as a single piece. 3D printed plastic parts can be useful for aerospace applications, such as aircraft interiors. The interior of a commercial aircraft cabin will need to be updated periodically, a process that may involve replacing components such as wall panels. The need for customization means that parts will usually be produced in small quantities. Fast deadlines are also essential.

When it comes to defense, 3D printing has the potential to change the way end-to-end parts for military equipment are manufactured. Current defense applications range from complex carriers and small surveillance drones, to jet engine components and submarine hulls. Electronic 3D printing is a young but growing area of interest for defense companies. With this technology, engineers are now able to design and manufacture prototypes of complex arrays and antennas themselves. For manufacturers, this means they can speed up the product development process by eliminating the need to outsource high-value projects to third parties. Aerospace companies can also benefit from 3D printing by using the technology to produce custom tooling such as templates and on-demand devices. Relying heavily on spare parts, airlines increasingly require short turnaround times for this application. To meet this demand, aerospace suppliers must find ways to provide manufacturing services faster. Additive manufacturing enables rapid production of spare parts when needed. This, in turn, reduces the need for huge inventories, helping to reduce inventory costs and ensuring that parts are produced locally. The spare parts supplier uses 3D printing to produce custom parts and tooling,

with the technology helping to significantly reduce lead times and simplify complex supply chain logic. With this strategic approach, the company is able to improve its turnaround time by rapidly producing spare parts for maintenance operations.

The aerospace and defense industry makes up a significant portion of the additive manufacturing market. The reasons for this are simple: additive manufacturing offers enormous value, from improving aircraft performance to offering a more agile approach to spare parts production. The move to manufacturing, however, requires additive manufacturing to overcome certain challenges. These include certification of 3D printed parts, better process repeatability and safety. Nevertheless, with significant investments in the development and certification of 3D printing processes and materials, the future of 3D printing for the aerospace and defense industry certainly looks bright (Zhang et al., 2021).

The automotive industry is a growing user of additive manufacturing. In fields such as motorsports and racing, design tools such as generative design and topology optimization are slowly changing traditional approaches to part design (Lee et al., 2017, Li et al., 2018). While prototyping currently remains the main application of 3D printing in the automotive industry, companies are increasingly finding other use cases, such as tooling. In addition, several automotive companies are beginning to find innovative end-use applications for 3D printing. Prototyping has become a key part of the product development process, offering a means to test and validate parts before they are manufactured. 3D printing offers a fast and cost-effective approach to designing and manufacturing parts. By eliminating the need for tooling, product teams can significantly accelerate product development cycles. The ability to build designs quickly gives designers more flexibility when testing multiple design options. 3D printing allows

designers to make quick changes and modifications to designs in a fraction of the time. 3D printing offers car manufacturers a cost-effective and flexible way to produce personalized parts for the interior and exterior of vehicles. Additive manufacturing enables the production of highly complex parts that are still light and durable. Prototyping has been the primary use of 3D printing for automotive applications. With the ability to produce multiple iterations of a design in less time, 3D printing is an efficient tool for product development. The technology has now evolved to the point where it can be used to create functional prototypes using high performance materials (Ligon et al., 2017, Liu et al., 2021, Wohlers, 2018, Zhai et al., 2014). With 3D printing technologies such as FDM and SLS, automotive companies are able to produce accessory tools at minimal cost, significantly increasing factory efficiency. The tools can also be customized for improved functionality at a significantly lower cost than conventional methods.

Within conventional manufacturing, mass production of spare parts is common. However, this often results in long delivery times and high inventory costs. Additive manufacturing has the potential to transform the way spare parts are manufactured and distributed — through on-demand manufacturing. This means that parts are produced locally, at the moment of demand. Coordinating supply and demand in this way could not only drastically reduce inventory costs, but also lead time to the end customer. One of the main obstacles to using additive manufacturing for manufacturing is the large production volume typically required for the automotive industry (over 100,000 parts per year). However, in recent years there have been great improvements in the speed and size of industrial printers, as well as greater availability of materials. As a result, additive manufacturing becomes a viable manufacturing option. 3D printing is

gradually changing the way vehicles are developed today. Whether it's a commercial vehicle, truck or race car, the technology offers automotive engineers and designers the tools to test the limits of design and performance. However, the key drivers behind the increased adoption of 3D printing in the automotive industry are the ability to accelerate time to market and reduce product development costs (Pasricha, 2018).

The medical and dental industry is one of the fastest growing industries adopting additive manufacturing. From medical devices to prosthetics, bioprinting, the applications of additive manufacturing for the medical industry are varied and wide. The geometric freedom afforded by additive manufacturing and the ability to provide more personalized patient care in a cost-effective manner are extremely attractive. Combined with CT scanning, 3D printing can be used to provide patient-specific solutions such as implants and dental appliances. 3D printing is an ideal technology for creating or optimizing designs for medical devices. Thanks to low-cost rapid prototyping, medical device manufacturers have more freedom to design new products, helping to bring new medical devices to market much faster. The medical industry can take advantage of 3D printing capabilities to create patient-specific devices. For example, devices such as prosthetics and implants can be produced faster and more affordably than traditional manufacturing methods. 3D printing can be used to create custom prosthetic and orthopedic devices from a number of certified biocompatible plastic or metal (eg titanium) materials. When it comes to implants, 3D printing is currently being used to make hip and knee replacements, skull reconstruction implants, and spinal implants. While 3D printing cannot yet be used to 3D print body parts, the technology can be used to create artificial living tissues that can mimic the characteristics of natural tissue. Known as bioprinting, this technology is used for

research and testing, with great potential for regenerative medicine. 3D bioprinting is already used to produce relatively simple artificial tissues and structures such as cartilage, skin and bone, as well as blood vessels and heart patches (Tamay et al., 2019, Wang et al., 2021, Yan et al., 2018).

Hospitals are increasingly incorporating 3D printing into their labs to create patient-specific anatomical models. Based on the patient's MRI and CT scans, these models are typically created using full-color 3D printing techniques such as injection molding to ensure they remain highly accurate and realistic. Surgeons can then use these 3D printed organ replicas to plan and practice a surgical operation before performing it. This approach has been proven to speed up procedures, improve surgical precision and minimize invasion. The primary benefit of 3D printing for this sector is its ability to provide more personalized healthcare, in addition to the ability to improve pre-surgical planning and drive device innovation. However, for 3D printing to truly transform the medical and dental market, there are still key challenges that will need to be addressed, most notably the certification of 3D printing processes and devices. Additionally, current trends suggest that the use of 3D printing in medicine and dentistry will continue to advance, paving the way for more advanced applications and new treatment solutions (Yan et al., 2018).

Further, to remain competitive in an ever-changing market environment, retailers and consumer-facing industries must be able to adapt in an agile manner to evolving consumer demands and industry trends. Additive manufacturing meets these needs, providing a cost-effective approach to product development, testing and manufacturing. From consumer electronics to toys and sportswear, key players in the consumer goods industry are increasingly recognizing 3D printing as a valuable addition to existing manufacturing solutions.

Before any new product can be launched, its design must first be validated, tested and approved. This process happens in the product development phase. Prototypes and models are a vital aspect of this process, as they are typically used for market research, testing and validation. 3D printing significantly accelerates this process by enabling rapid production of prototypes and models. Using the technology, product designers and engineers are able to develop and test multiple iterations of repetitive testing in a much shorter time frame. Perhaps the biggest impact of 3D printing for consumer goods lies in the potential to create personalized products, tailored to the needs of consumers. With traditional manufacturing, where products are usually mass-produced, producing customized products in small batches is very inefficient and not cost-effective. These limitations are eliminated by additive manufacturing. Companies are already using opportunities to provide customized service to customers (Tay et al., 2017, Wu et al., 2016).

The industrial goods sector includes the production of machine components, tools and equipment used in the production of other goods. With increasing production costs and the digitization of production, industrial manufacturers must constantly evolve to maintain operational agility and reduce costs. Manufacturers are therefore increasingly turning to 3D printing to remain agile, fast and innovative. As we've seen in other industries, rapid prototyping is a key use case for 3D printing for the industrial goods sector. Design changes that would take months using conventional manufacturing methods can be implemented much faster, often in less than a week, using 3D printing.

Most companies in the industrial goods sector prefer 3D printing the most because of its ability to shorten delivery times. Because 3D printing requires no tools, manufacturers can reduce the time it takes to produce parts,

bypassing the time-consuming and expensive step of tooling. 3D printing is a cost-effective technology for producing parts with complex geometries. Designs that would otherwise be impossible to produce with conventional manufacturing can now be produced using 3D printing. Because 3D printing can produce physical parts from digital files in hours, companies can take advantage of a new model of on-demand part manufacturing. Major industrial goods companies are already exploring additive manufacturing as a means of producing end-to-end parts. The ability to 3D print production aids, such as templates, gauges and accessories, opens up new opportunities for manufacturers of industrial goods. In addition to templates and accessories, 3D printing is revolutionizing the production of hard tools such as molds, which are used in injection and die-casting. Traditionally, CNC-milled molds can undergo multiple design iterations, taking weeks, if not months, before the final design is achieved. This results in a time-consuming and very expensive process with significant material waste. Now, 3D printing technologies can be used instead, allowing tooling companies to not only reduce material waste but also improve mold functionality. This can be achieved by integrating cooling channels of a more complex shape into the design, thereby significantly improving the cooling characteristics of the mold. Thanks to on-demand 3D printing, manufacturers can produce spare parts quickly and economically. This approach is useful, for example, when obsolete equipment requires a replacement that may be out of production or difficult to obtain. 3D printed parts are said to reduce costs and lead times from weeks to hours while bringing greater operational agility. For industrial manufacturers, 3D printing offers new ways to improve production processes, develop new business models and drive innovation (Ngo et al., 2018).

#### 4. Advantages and disadvantages of techniques and processes in the industrial application of 3d printing

The main advantages of 3D printing are indicated to be cost reduction, less waste, time reduction, gaining competitive advantage, error reduction, confidentiality, on-demand production. The advantages of 3D printing make it one of the most promising technologies. Additive manufacturing technology is one of the biggest advantages of 3D printing, it opens up a completely new way of creating products and offers many advantages over traditional manufacturing methods (Gao et al., 2015, Gibson et al., 2015, González-Henríquez et al., 2022)).

Many different types of 3D printing technologies are currently available. Through rapid design, a high level of accuracy and the ability to make decisions based on information, the following advantages of 3D printing make this technology a future perspective for many companies around the world, but also highlight its importance in future production techniques: cost reduction, shorter production time; waste reduction; creation of more pronounced competitiveness and advantages in relation to rivals; the possibility of errors is reduced in the production process; confidentiality of intellectual property because everything remains within the company; production processes on demand. These are the most important and main advantages, and they will be described in more detail below (Hao et al., 2020).

Cost reduction (less machine, material and labor costs). Cost reduction is of great importance for business unrelated to the manufacturing sector. 3D printing can help reduce those costs. Machine operating costs play a very important role in the total costs

of the production process. While the energy required to create parts in an industrial environment can be high, the ability to develop and create complex parts and products in one step creates an increased level of efficiency and saves time. Therefore, the cost of running the machines is offset by the savings made during the production process. One of the good things about 3D printing is the fact that labor costs are low, unlike traditional manufacturing where different people may be required to operate different machines or a production line is needed to put the product together. Each 3D printer will require an operator to start the machine and start the automated process of creating the uploaded design. Therefore, labor costs are significantly lower than traditional production. The range of 3D printer filaments used for 3D printing is growing and this has allowed the price to decrease in recent years.

*Time reducing.* One of the great advantages of 3D printing is that parts and products can be produced much faster than with traditional methods. Complex designs can be created as a CAD model and then transformed into reality in just a few hours.

A more pronounced competitive advantage. By being able to reduce the time of the prototyping phase, companies around the world and from various industries can deliver better, improved products in a shorter period of time. But it also allows products to be developed early, more often prototyped until the product is perfected and ready for production allowing for an efficient product launch. Being able to create life-size prototypes allows designers to think differently about the products they design. One of the benefits of 3D printing is that it allows for the rapid creation of products that people can physically hold, eliminating any confusion or miscommunication. While it may be a prototype and open to change, it at least provides a glimpse of what the product

will look like, offering a truer representation than a description.

*Testing the market with 3D printing.* Understanding whether a product will be successful requires a lot of research, especially when it comes to traditional manufacturing methods. However, creating prototypes through 3D printing will allow companies to get feedback from potential customers and investors in a way that could never be achieved before. The product can be customized and changed up to the last minute, which is something that traditional manufacturing methods do not offer. This means that 3D printing offers a unique and valuable way to identify whether a product has the potential to go to market and be successful at the same time.

*Reduction of potential errors.* When it comes to designing parts and products, designers must consider efficiency. Many parts and products require a large number of steps using traditional manufacturing methods to be produced. Therefore, each step can lead to an error, with the risk of starting over, which can lead to problems with the entire production process. A one-step manufacturing process is more beneficial. There are many industries that have a long and multi-stage production process. One of the advantages of 3D printing is that the product is created in one step, without operator interaction during this process. This removes the dependence on numerous production processes and improves control over the final product. During the traditional manufacturing process, faulty prototypes cost time and money. 3D printing can remove risk because the design can be verified by creating a production-ready prototype before moving on to the final creation. This helps build confidence in the design before investing.

*Intellectual property protection and data confidentiality issues.* Continuous prototyping and manufacturing within the company using 3D printers ensures that the

design never leaves the company premises, protecting intellectual property. Every innovative design is kept within the company, so there is no longer any need to pay attention to confidentiality issues.

*Production processes on demand.* The possibility of complete freedom in design is a great advantage of 3D printing. It also allows designers to customize the design. As 3D printing is perfect for one-off manufacturing and building individual parts in a single process, this means that customization can be exploited. Therefore, many industries, such as medical and dental, have embraced 3D printing and design due to the ability to create custom implants and aids. Traditional methods relied on molds and cutting, making customization a time-consuming process.

But there are also evident disadvantages of 3D printing, which must be taken into account. Some of the shortcomings noted are: the initial costs of purchasing a 3D printer (the return on investment is fast and efficient, but it is still necessary to make an initial investment); 3D printing in manufacturing very often requires post-processing to be of real use; the time factor is also of great importance in the sense that depending on the size and quality of the printer, printing can take from several hours to days, but when the printer makes a mistake when it is almost finished printing, it has to be started from the beginning; utilization by the 3D printing process requires a number of special skills related to 3D modeling; 3D technology can create product designs and prototypes in hours because it uses only one step. It eliminates many stages used in traditional manufacturing. As a result, it does not require much labor cost. As such, the adoption of 3D printing can reduce manufacturing jobs. For countries that rely on large numbers of low-skilled jobs, a decline in manufacturing jobs could

dramatically affect the economy (Mahmood et al., 2022).

## 5. Conclusion

It can be summed up in a barrage of concluding remarks that 3D printing in production goes beyond the limits of rapid prototyping. New opportunities for mass production and fully virtual inventory could soon become a reality. It points to the value of 3D printing for existing production flows. Although there are several drivers of this transition, they can be summarized in two groups. Process innovation refers to the greater flexibility and agility that 3D printing brings to manufacturing and supply chains. It includes digitization and decentralization of production, as well as the ability to create tools and spare parts on demand. Product innovation refers to expanded design capabilities to create innovative new parts and products, including complex lattice structures and other geometries, weight reduction, customization, part count reduction, and multi-material 3D printing (Mallakpour et al., 2021). The potential of

3D printing technology is just beginning to be fully realized.

There is a wide and varied range of benefits of 3D printing. Many different industries are starting to introduce 3D printing into their processes in an attempt to get the maximum benefit from using the technology. The ability to print complex shapes and interlocking parts without the need for any form of assembly is what makes 3D printing so unique. It is possible to create small, complex shapes at very low cost and in a short time. The ability to develop and produce objects of various shapes without the need for special tools offers businesses a greater level of flexibility when it comes to production and helps reduce costs. A significant advantage of 3D printing is that it improves innovation and performance of on-demand production. Despite the fact that 3D printing is a relatively new technology, it has quickly become significant, primarily due to cost reduction. Also, this technology is becoming more accessible to almost everyone. It can be said that 3D printing has revolutionized the industry in an extraordinary way.

## A CONCEPTUAL REVIEW ON THE NECESSITY OF 3D PRINTING FEATURED CONSTRUCTION IN ERITREA

**Abstract:** Since the end of 2022, Eritrea is seeking for a drastic change in technology and development as the colonization and subsequent wars have lasted for more than a century eventually come to an end. As a developing country, the need for human shelter raising and consequently expecting rapid change in the building construction methods and the relevant real estate deals. Thus, the adaptation of fast building techniques aids to stabilize the housing issues and to mitigate with currently facing tenant problems. This paper investigates the effect of introducing 3D printing technology in construction sector, and to create an awareness amongst the builders and investors about the advantages and disadvantages of 3D printing in terms of many different materials and methods implicated in the construction practices. Further, it clarifies the challenges to be faced besides the benefit of saving potential time coupled with effective cost reduction. So far in Eritrea, conventional building methods are mostly practiced, this work focused on a better validation with the advanced printing technologies. Furthermore, the ultimate objective of this research is to develop a theoretical frame work that open an eye for investors, who can support the initial phase of the printed house as a model and extends for the future developments of housing projects. In addition, it convinces the reader through accepting that the construction facilitated with 3D printing is an improved practice and fastest way to cope up with currently existing housing problems.

**Keywords:** 3D printing in construction, challenges in construction, conventional building methods, Effects of 3D printing, time and cost benefits

### 1. Introduction

Modern building techniques are around for higher output and operations which aim to boost the productivity of construction, efficiency, user satisfaction, environmental performance, better quality, sustainable development and predictability of delivery

time (Bilal A et al 2020). They are capable of maintaining different factors and avoiding steps in construction to overcome the problems that could a raise from the conventional method. Some of the problems are thought by Nils O et al 2021 they have environmental friendly problems like noise and dust along with resource-saving problems such as large template quantity and

low construction accuracy. Industries have begun to re-establish their production systems with the developing technology (Asena K et al 2022). Currently we are at the era of Industry 4.0, sometimes referred to as the Fourth Industrial Revolution builds upon the established digitalization but includes a synthesis of technologies transforming entire systems of production, management and governance. Currently, emerging technologies include materials science, quantum computing, artificial intelligence (AI), Internet of Things (IOT), autonomous vehicles, robotics and 3D printing (Nils O et. al 2021). Applying the technologies, Industrialization of the building and construction process is aimed in increasing the productivity and efficiency of the building houses.

One of the current trends of modern construction is concrete 3D printing, also known as rapid prototyping technology, which is computer-controlled technology that uses 3D data and makes an object from a three-dimensional model by deposition of materials (Lotfi and Sameh ,2020; Nils and Ali,2019; Amr A et al, 2021). The first 3D printer was invented in 1984, since it was the fastest growing technologies by 2000, has become relatively friendly to use, as it allows to create the design on the computer, and comparatively the production cost was very less as it utilizes plastics and waste materials to form the concrete of 3D houses. And suddenly it became affordable and viable for a wide range of design, models, etc (Abhishek and Aditi, 2021; Izabela H et al, 2016). 3D printing technology is increasing its impact from time to time. Up to now Intentionally or not almost everyone must have enjoyed the great impact of this technology. (Jatin A et al 2021, Andreas and Miranda 2013), listed out some of the major sectors that imply to the future of 3D printing technology like prototype making, bio-organ printing and dental implants, safety, domestic applications, parts

manufacturing for industries, food printing, jewelry designing and housing and construction in which being economic and fast is the primary factor where existence and demand resides on.

Construction projects can have different degrees of making building jobs, As Nils O et al 2021 supports construction industries are generally categorized into as traditional, non-volumetric pre-assembly, with volumetric pre-assembly volumes and modular building. Traditional, “one-of-a-kind” construction utilizes component manufacture and sub-assembly in which raw materials and components are brought to the site where the value-adding actions are carried out. (2) Non-volumetric pre-assembly describes when two-dimensional elements are prefabricated and assembled on-site (walls, floors, etc.). (3) With volumetric pre-assembly volumes of specific parts of the building are produced off-site and assembled onsite within an independent frame. (4) Finally, modular building describes construction where most of the production is carried out off site leaving only assembly and finishing operations to take place on-site.

3D Printing in the construction industry is revolutionary and enormously getting attention from every part of the construction industry of the world. However, a 3D concrete printer costs a lot, ranging in between \$180,000-1 million US dollars (woodgroupmortgage.com), such a huge money usually is possessed by construction industry (Yanhua Z,2022). The construction industry has an annual revenue of nearly 10 trillion USD, which represents around 6% of the global GDP. Indeed, the engineering and construction industry is a cornerstone of the national and international economy. Lowering labor for safety reasons, reducing construction time on site, reducing production costs, and/or increasing architectural freedom provide an additional income to the construction industry (Lotfi

and Sameh 2020). 3D printing is a promising technology for buildings. Compared with traditional buildings, 3D building printing can save 50%-75% of the time value, 50%-80% of the labor cost and 30%-60% of the

material cost. According to experts' estimation, 3D building printing can save 30%-50% of the total cost (Amr A et al, 2021).

**Figure 1 (a-b).** 3D concrete printing in the construction application (source: googleimages)

The currently practiced construction technique in Eritrea is modular building. It is implemented by creating the parts required for the building off-site i.e. governmental workshops and then brought them on-site. This technique applies partially 3D printing approach to build the components to be assembled. Further, it requires a way to drive the parts to construction site by the trucks, which require the consumption of fuels. Finally, it involves some cranes and man power to assemble the parts. Xtreme et al 2021, clearly stated that concrete 3D printing can be preferred over precast, hence it enhances additional benefits in which it doesn't require assembly and can be set up in remote areas where normally trucks cannot drive.

### 1.1. Types and methods

The concrete 3D printing equipment consists of three parts: frame structure, control system, and feeding and extrusion system. The frame structure is responsible for the support and movement of sprinkler head device in space and the control system controls the movement of the printing device and the extrusion of concrete while the feeding and the extrusion system mainly to solve the problem of uneven feeding caused by concrete pumping and improve the extrusion accuracy to achieve precise printing as shape and diameter of the extrusion nozzle are of great importance (Yanhua Z et al 2021). Till now there exist two types of systems majorly: gantry system and robot system (Lotfi and Sameh 2020, Jian Y et al 2022).

Robot system consists of a cylindrical like 6-axis robotic arm which has several joints enabling it to telescope and rotate with

multiple degrees of freedom, and a rotating printer nozzle attached at the end (Xtreme et al 2021). However, it is unsuitable for large buildings as it suffers from limited work space (Lotfi and Sameh 2020). The gantry system is a common system which allows Cartesian motions of the nozzle in the 3 axes (x, y, z). This comes in rail and fixed frame work version. The challenges with this

technology include transportation, installation and size. Gantry printer are usually used because they are easily scalable in size and they are superior to robotic printers if the design of the printer target is not complex. This is because the robot costs more and the load on the robot arm is usually lower than gantry printer (Jian Y et al 2022).

**Figure 2.** Gantry system (a) and Robot system (b) (source: www.Google.com)

Robot system consists of a cylindrical like 6-axis robotic arm which has several joints enabling it to telescope and rotate with multiple degrees of freedom, and a rotating printer nozzle attached at the end (Xtreme et al 2021). However, it is unsuitable for large buildings as it suffers from limited work space (Lotfi and Sameh 2020). The gantry system is a common system which allows Cartesian motions of the nozzle in the 3 axes (x, y, z). This comes in rail and fixed frame work version. The challenges with this

## 2. Implementation of 3D Printing Technology

### 2.1. Methods concrete of 3D printing and its Pros and Cons

The methods of implementing a 3D concrete printing are generally categorized into five classes based on the working principle and raw materials required for printing. Thus they arise to different resolutions and strength. These methods are FDM (Fused Deposition Modelling), SLA (Stereolithography), SLS (Selective Laser Sintering), EBM (Electron Beam Melting), LOM (Laminated Object Manufacturing). The table 1 summarizes the working principle, raw materials to be used, the strength and resolution of the printed concrete according Asena k et al 2022. Moreover, the roughness of the printed concrete is provided so as the attractiveness of the printed concrete can be imagined.

**Table 1.** Different methods of 3D concrete printing

Method	FDM	SLA	SLS	EBM	LOM
Working Principle	Extrusion Stacking Technique	Solidification of photopolymer material with UV light	Sintering of powder with CO <sub>2</sub> laser	Electron Beam Melting	Laser Cutting and Gluing of Sheets
Material Used	ABS, polyamide, polycarbonate, polyethylene, polypropylene and investment casting wax.	Resin-based materials, acrylic, epoxy, Polypropylene.	Polyamide, polystyrene, carbon fiber and aluminum added polyamide, polycarbonate, stainless steel, cobalt chrome, nickel chrome, titanium, ceramics.	Cobalt chrome and titanium alloys, ceramics.	Paper, plastic foam, metal and ceramic powder impregnated materials.
Resolution	Medium	Good	Weak	Weak	Medium
Strength	Good	Medium	Good	Good	Medium
Roughness	Medium	Good	Weak	Good	Medium

**Figure 3.** Geometric freedom of complex structures using 3D concrete printer (a, source:www.sculpteo.com), (b, source:www.googleimages.com), (c, source: www.sculpteo.com) and (d, source:googleimages.com).

**Table 2.** Advantages and disadvantages of concrete 3D printing technology.

S.No	Advantages	Disadvantages
1	Eco-friendly: Designing zero waste projects, reducing carbon emissions, and using innovative and recycled materials with new technology to enhance sustainability can achieve a type of future housing consistent with trends towards sustainability within the forces of demand (Mahdi R M 2021).	Unemployment: In Eritrea Majority of the local people who are skilled in conventional method of building which has no alternative skill. But Using 3_D printing unemployment would arise.
2	Accuracy: According to the preset computer program, layer by layer construction, to a large extent to avoid human error, to ensure the quality of the finished product (Jian Y et al 2022).	Power: 3D printers consume way more energy than what we can think of as according to a research it consumes 100 times more electrical energy compared to conventional methods (Abhishek and Aditi 2021).
3	Over All Cost: Compared with traditional buildings, 3D building printing can save 50%-75% of the time cost, 50%-80% of the labor cost and 30%-60% of the material cost. According to experts' estimation, 3D building printing can save 30%-50% of the total cost (Jian Y et al 2022).	Maintenance Cost: High initial costs for equipment and ongoing maintenance costs (Amr A et al 2021).
4	Unusual shapes (complex geometries): 3D printing can produce shapes that are impracticable or too costly to manufacture by increasing degree of freedom (Abhishek and Aditi 2021).	Knowledge: Skilled labours are required as the knowledge of CAD and 3D Printing software are required (Abhishek and Aditi 2021).
5	Immediacy: 3D printing can be done according to different requirements, thus reducing inventory, and can also be formed once, without assembly, realizing immediacy from printing to delivery (Jian Y et al 2022).	Reliability: Limitation in material flexibility means that only specific material can move through a machine and can still be used in the desired manner without damaging or deforming the specific machine (Amr A et al 2021).

**2.2. Challenges in 3D printing technology adaptation**

Despite of the difficult situations occurrence Prototypes and projects built over the past few years have demonstrated both the viability and potential of 3DCP technologies

to be as a solution for any construction company (Nadja et al 2020). Any construction sector has to face the challenge that is arising and so for the 3\_D printing construction sector. As LotfiRomodhan et al 2020, challenges are categorized in to four classes: material, printer, design and

construction, and regulations. The material challenge includes printability, build ability and open time.

Printability and build ability refer to the ability of the extrusion nozzle to allow the thick paste to pass through and result the material to mold or maintain shape. At the end the period required for printability and build ability will be known as open time, which will decide the acceptable tolerances as delays may cause concrete hardening. The printability refers to the ability of the extrusion nozzle to allow the thick paste to pass through while the build ability is the ability of the material to mold or maintain shape and, open time is the period when the printability and build ability are consistent with in acceptable tolerances as delays may cause concrete harden. The second challenge is the cyber security, where it needs a special concern as the 3D model is automated and all information is available, size of the construction project in relation to the size of the printer is also another challenge. Design and construction is the third challenge. This includes exclusion of building services, structural integrity and suitability of the construction site. Exclusion of building services, such as electrical and mechanical, is a challenge. Constructions are held in an open environment where environmental temperature is a main factor to be considered during operation. Areas such as the Danakil Depression in Eritrea will require a special care during 3D printing. Additionally, the site conditions may be irregular that hinder the movement and installation of the 3D printer. The fourth challenge is the Lack of codes and regulations pose additional challenges to 3D printing in construction as it is any newly developing technological inventions serious design of codes and regulations requires a special attention. Moreover, Guangchao et al 2019 describes there is also an additional challenge to be faced using real time detection and adjustment function of 3D printing system, the printing speed, the

motor state and the system temperature are detected and adjusted that becomes another challenge to face.

### **3. Economical and Other Conservative Benefits**

#### **3.1. Economical Benefits**

Since every 3D printing technology makes use of different raw materials (polymers, sand, clay, concrete, concrete and gypsum mixture, cement mixtures, destroyed construction wastes), where some are to be collected in open environment and some are available at lower costs. Thus it lowers the expense of the printed house (Amr A et al 2021) but it makes it difficult to estimate the overall cost unless there are specific category and price ranges (Ahmed S et al 2019). Moreover, different method (FDM, SLA, SLS, LOM and EBM) is also another factor to be considered as differ in their working principle and raw material demand. The destruction and restoration of buildings follow a large amount of waste where they are disposed usually. 3DCP can make it get recycled and to be used as a raw material in 3D concrete printing decreasing in building expense (Abhisheke P et al 2021). The reduction in construction time is translated into lower costs as labor rates does not require that much time (Xtreme et al 2021). This is because it controls the main factors that affect the cost of the construction, such as : less formwork, less labor (it only takes two to four people to set up and operate the 3D concrete printer), shorter supply chain, lower logistics costs (3DCP equipment can be easily transported from one site to the next), design flexibility (geometric freedom; e.g., the ability to print houses with walls that are curved or straight), faster construction time, and greater efficiency (minimal waste of materials) (R M Mahdi 2021). The presence of Eritrean cement factory i.e. GEDEM cement factory will

make the construction expenses get lowered. While the people income is limited as a result of the neither peace nor war situations but with this Eritrean new development and technology phase, the income of the people is expected to increase and thus citizens and nationals would afford the house in an easy manner increasing the demand of concrete printing.

### **3.2. Time Benefit**

3DCPs are well known with the potential to dramatically lower the cost of construction, with respect to the foundation, walls and roof of the house. The time required to print the outer shell of a small-sized house (e.g., 1,200 square feet) – foundation, walls and roof - can be as little as 24 hours (possibly spread across several days depending on local weather and other conditions) (R M Mahdi 2021). In a similar manner to achieve with conventional construction methods it takes four to six months. It's a time saving due to printer's ability to operate 24 hours per day for the whole week. Thus contract delays related to deliveries and coordination are accomplished on time (Amr et al 2021). All in all, the reduced time results from not having to use concrete form molds, eliminating the time required to frame a house, the speed of 3DCP and reduced labor per house (xtreme et al 2021). Moreover, 3DCP is driven by computer aided Design (CAD) building information Modeling (BIM) software that also speeds up construction instead of printing out hard copies of architectural plans for various trade workers to use to construct a building (Xtreme et al 2021). This may lead to the easy and fast development of new Asmara city as the old town is collapsing which is considered as a monumental to the state.

### **3.3. Case studies of 3D Printing in Construction**

According to Mahdi RM 2021, “Tabasco”, Mexico construction aiming to build 50 homes to support poor communities in the country where each house total area of 120 m<sup>2</sup> consisted of 55m<sup>2</sup> internally designed of a living room, kitchen, bathroom, and two bedrooms where they were provided at a cost of \$6,000 per residence. Which can be concluded that the cost is affordable for the citizens. The residences were characterized by large curved rooves that extended at the front and back to act as a buffer against heavy rain, and the bases of structures and walls were strengthened against seismic activity to increase durability. Perforated concrete blocks along the top of the walls are used for natural ventilation, while the interior space is open plan, for increased airflow, with interior walls curved for easy cleaning.

In 2014, the Chinese WinSun Decoration Design Engineering Company has printed ten houses and each is approximately 100 m<sup>2</sup> in only 24 hours. These houses are constructed from waste material made of recycled rubble, fiberglass, steel, cement, concrete, and binder and the cost of each small dwelling is less than \$5,000 because of the fast process and the low labor costs. In 2015, the WinSun printed an apartment building of six stories (1,100 m<sup>2</sup>) fabricated using construction waste of concrete, fiberglass, sand, and a special hardening agent. (is is considered valuable in terms of recycling materials. Accordingly, 60% of the materials are needed to construct a home with 70% of the time saving compared to conventional construction [Rawan A et al 2020].

Dubai's Office of the Future was printed using WinSun's tilt-up technology where the floor, walls, and ceiling are all printed on their side layer by layer and then tilted vertically. The 250 m<sup>2</sup> office is constructed

and completed within 17 days at a cost of \$140000 using a special cement after being tested in china and United Kingdom. The cost was cut by more than 50% compared to conventional buildings of similar size [Rawan A et al 2020].

According to Alshugairi (ARAM TV, 2019), the kingdom of Saudi Arabia, the ministry of settlement, it took to about 26 hours to build a house using a 3D concrete printer as it was assembled on conventional foundation which took additional 12hours. Further he specified the technique applied and the duration of the process in relation to the ability of 3D printer.

India is one of the world's largest nominal GDP and third largest by purchasing power parity by 2017. It is one of the fastest growing major economics and is considered a newly industrialized company (16) Thus building expense and material cost is expected to be lower than that of the Eritrean expense. Abhishekhe P et al 2021 evaluated time and cost effectiveness of a 600 square feet in comparison to both building methods i.e. conventionally built and 3D build of the same design living room. Using a conventional method, the requirement of additional expenses makes the price raise to reach to about 811,330 Rupees while 550,000 Rupees was the estimated cost using 3D printing. So there is a cost difference to about 261,330 Rupees. Considering the governmental currency rate of 69.5135 Indian Rupees per unit dollar, there is a difference of \$ 3,760. Comparing to "Tabasco", Mexico construction (Mahdi RM 2021), its more than half the selling price is saved.

Chinese construction company HuaShangTengda constructed a 400 square meter mansion using 3D printing Tongzhou region near Beijing, China with in just 45 days. The mansion was an earth quake proof which can with stand up to 8 Richter scale. The walls are of 250mm thick and were printed using approximately 20 tons of C30-

grade concrete. This grade of concrete is usually used in paving roads and providing it with seismic resistance (William J)

### 3.4. Comparison Between Conventional and 3D Printing featured Constructions

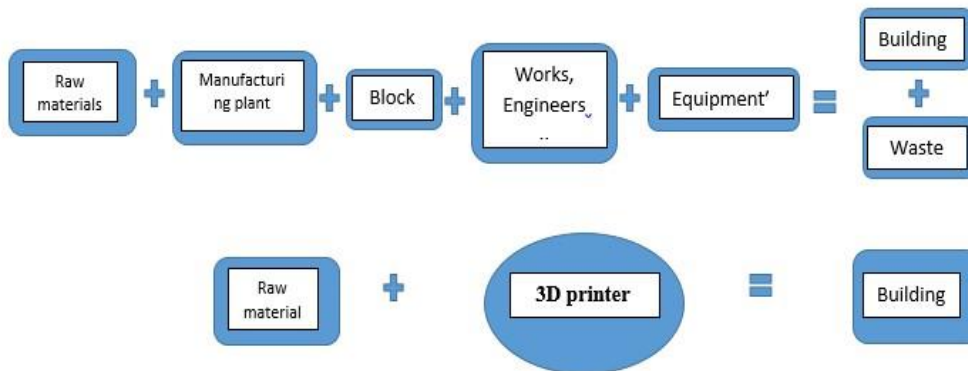

The use of 3DCP is believed to offer solutions to the construction of more affordable housing in the world, particularly for remote, isolated communities having limited construction infrastructure reduced construction time, labor savings, lower materials costs, possible use of local materials for construction, improved labor safety, increased design opportunities, less waste, scalability and reduced environmental impact (Xtreme et al 2021). In conventional method raw material require different packaging, storage space, transportation, and operating condition (Qaisar M et al 2021). Upon construction the need for foundation and hardening it laps for several days. Building of bricks and wall formation along with hardening it takes a long time. Even architectural models are not easily constructed since it takes time (Mahdi R M 2021). Additionally, some studies indicate that 3DCP wall patterns may afford similar benefits as conventional construction related to thermal insulation (Xtreme et al 2021). The conventional method involves human resources in different locations of the structure. Thus, they are time-consuming and expensive. The 3D printer on the other hand shows how the printer is both a tool and a manufacturer. The less involvement of the user in the printing process, the smoother the process is automated (Ahmed S 2019). Building waste many a time circumscribed concrete, bricks, metals, glass, plastics, wood, asphalt, and more. This waste is frequently disposed in landfills. It does not only pollute the land and air, but also the transportation required to remove such waste has a significant impact on the environment

as well upon building in destroyed sectors. As per the Environmental Protection Agency, there were as huge as over 170 million tons of debris generated in the construction and destruction of buildings alone in the U.S in the year 2003, of which

61 per cent were solely from the residential building (Abhisheke et al 2021). 3D printing can also be used to print home decors, furnishing products and other structures for architectural detailing [MajuR et al 2019].

**Figure 5.**Traditional method (above) Vs 3D concrete printing (below) method

#### 4. Conclusion

To sum up all the above, concrete 3D printing is increasing its demand in developing countries specially Africa. The 3D concrete printing technology is more advantageous compared to conventional

method of building. It is faster and more accurate in addition to complex geometric freedom. It is also economical and time saving building method. Concerning about cost the 3D printed house is mostly 30-50 % less of the same designed house built using conventional method. The cost reduction is

because it increases in labors demand. When it comes to waste materials, this technology creates only one third of the waste generated using conventional building methods. This would lead to a permanent housing solution in Eritrea and developing countries. From Economical point of view, Affordable house is the main problem in African countries as the population income is limited, but the rise of 3D concrete printing would minimize housing problems and create affordable houses easily. This will be an investment opportunity for investors in very part of the world. The country is still full of natural resources and a new method of printing could be discovered if a detailed research is conducted on the resources available so that

it can enhance additional cost reduction and increase in the investors revenue. All in all, this construction technology would create a stable nation and increase in citizen's advancement, while the nation increases in infrastructure level. At the end, from the authors point of view it is expected that construction companies should go for 3D printing procedure to construct their future structures and increase in their capital.

**Acknowledgment:** Authors would like to convey their gratefulness to their family members for their persistent support. Authors extent their thankfulness to all department staff members, Dept. of Chemical Engg, MCoET.

## ROUTING FLEXIBILITY ANALYSIS OF DIDACTIC FLEXIBLE MANUFACTURING CELLS USING EVIDENCE NETWORKS

**Abstract:** Flexible manufacturing systems are becoming increasingly popular in modern industry, providing flexibility in producing different products and quick adaptability to changes in the production program. Didactic FMC (DFMC) are small manufacturing systems used for educational purposes, providing students with practical experience in production. DFMC systems are the basic element in learning new concepts of Industry 4.0. This paper explores the flexibility of routing components in DFMC systems using the Dempster-Shafer theory of belief functions and evidence networks developed based on this theory.

By using the Dempster-Shafer theory, we evaluate the flexibility of routing in the system for producing different products, i.e., the system's ability to adapt to changes in the production program according to the concepts of Industry 4.0. The analysis of routing flexibility allows for identifying critical points of the system and suggestions for improving system efficiency.

The results show that routing flexibility is a key factor for the efficiency of the DFMC system. The Dempster-Shafer theory provides a precise analysis of beliefs based on various input parameters, which contributes to the precision and reliability of the analysis of routing flexibility of DFMC system components. This paper contributes to the understanding of routing flexibility and provides guidelines for further research in this area.

**Keywords:** Flexible Manufacturing Systems (FMS), Flexible Manufacturing Cell (FMC), Didactic FMC - DFMC, Routing Flexibility, Dempster-Shafer Theory

### 1. Introduction

Flexibility is one of the key goals of every manufacturing system and as such represents a critical measure of its overall performance (Buzacott, J. A., & Mandelbaum, M., 1985). It is defined as: "Flexibility is defined as the ability of a manufacturing system to cope with changing circumstances or instability caused by the environment" (Gupta, Y., Goyal, S., 1989). Changes that lead to the need for flexibility of technological systems

can be internal (machine or material handling system breakdowns or some operational variability) or external (changes in the requirements of external customers, changes in the material of the parts being produced, etc.) (Buzacott, J. A., & Mandelbaum, M., 1985). According to the classification given in (Browne, J., Dubois, D. et al., 1984), FMS flexibility can be: Machine, Process, Product, Routing, Volume, Expansion, Operation, and Production flexibility.

The purpose of this paper is to introduce students to the flexibility of routing through an example of a didactic flexible manufacturing cell (DFMC) (Mirkov, G., 2022) by applying Artificial Intelligence (OpenAI, 2021) and modern mathematical tools such as Dempster-Shafer theory of belief functions (Shafer, G., 1976; Djapic, M., 2005) and Evidence Networks (Shenoy, P.P., 1992; Djapic, M., Lukic, Lj. etc., 2019) which are developed based on this theory.

In the educational process, the aim of routing in DFMC can be to increase the practical application of theoretical knowledge and skills that students acquire through lectures and exercises. Therefore, the selection of an appropriate group of parts for routing in FMC can be a crucial factor for the success of this goal. The application of Dempster-Shafer theory for analyzing the flexibility of routing in DFMCs can help optimize the process of selecting a group of parts for routing in FMC, considering the uncertainties and ambiguities that often arise in this process. Dempster-Shafer theory is based on the theory of belief, but unlike classical probability theory, Dempster-Shafer theory can take into account incomplete and contradictory knowledge.

Therefore, this paper will discuss the application of Dempster-Shafer theory in analyzing the flexibility of routing in DFMC, with a focus on selecting the best group of parts for routing in FMC in the educational process. Through this analysis, researchers will have the opportunity to assess the effectiveness of different routing strategies, and thus choose the best strategy to achieve the goal of routing in the educational process.

## **2. Dempster-Shafer Theory of Belief Functions**

Making conclusions (reasoning) about certain situation from the real world is often in difficult circumstances with insufficient

knowledge, no clearly defined criteria and mutual antagonism. Information about evidence can come from different resources: based on a person's experience, from signals recorded by appropriate sensors, from the contents (the context) of published papers and so on. Such evidence is rarely clearly delimited; it's often incomplete, ambiguous in its meaning and full of flaws.

Dempster-Shafer belief function theory provides powerful tools for mathematical presentation of the subjective (opposite of what probability theory is based on) uncertainty while it relies mainly on possibility of explicit definition of ignorance (Shafer, 1976). This theory is intuitively adapted formalism for reasoning below uncertainty limit. It, actually, represents the generalization of Bayesian theory of conditional probability. As such, it provides formally consistent method for interpretation and connection of evidence, which inside itself carries some degree of uncertainty, and in addition, provides getting meaningful answers to posed questions using only partial evidence. Complete records can be used only in necessary cases.

### **2.1. The Basic Concepts of Belief Functions**

Model of the belief function consists of variables, their values and the evidence, which supports the value of variables. Variables represent specific questions regarding the aspect of the problem under consideration. Given questions are answered using data originating from various sources, i.e., from context of published papers, from measurement data, from expert opinions, etc. Fully integrated support to the sought answer is called evidence.

Evidence can be represented by belief functions, which are defined as follows:

Definition.1. (Shafer, G., 1976) Let  $\Theta$  be a finite nonempty set called the frame of discernment, or simply the frame. Mapping

Bel:  $2\Theta \rightarrow [0,1]$  is called the (unnormalized) belief function if and only if a basic belief assignment (bba)  $m: 2\Theta \rightarrow [0,1]$  exists, such that:

$$\sum_{A \subset \Theta} m(A) = 1$$

$$Bel(A) = \sum_{B \subset A, B \neq \emptyset} m(B)$$

$$Bel(\emptyset) = 0$$

Expression  $m(A)$  can be viewed as the measure of belief which corresponds to subset  $A$  and takes values from this set.

Condition (1) means that one's entire belief, supported by evidence, can take the maximum value 1, and condition (3) refers to the fact that one's belief, corresponding to an empty set, must be equal to 0.

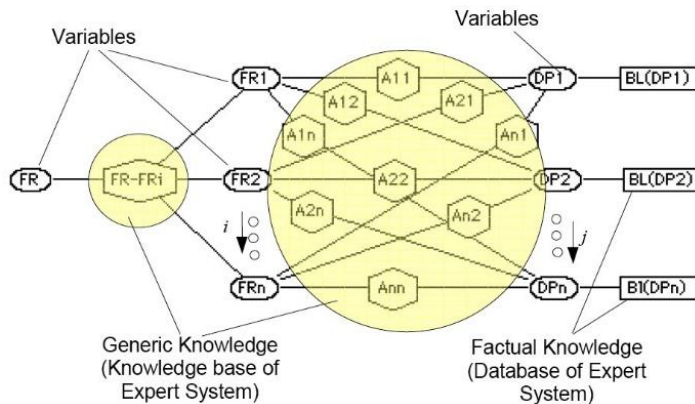

Value  $Bel(A)$  represents the overall belief corresponding to the set  $A$  and all of its subsets.

Each subset  $A$  such that  $m(A) > 0$  is called a focal element.

The empty belief function is the function which satisfies  $m(\Theta) = 1$ , and  $m(A) = 0$  for all subsets of  $A \neq \Theta$ . This function represents total ignorance about the problem under consideration.

### 2.2. What are the Evidential Systems? (3)

Valuation Based Systems - VBS is an abstract framework proposed by Shenoy (Shenoy, P.P., 1992; Djapic, M., Lukic, Lj. Etc. 2019) for representing and reasoning on the basis of uncertainty. It allows representation of uncertain knowledge in various domains, including Bayes' probability theory, Dempster-Shafer's theory of evidence which is based on belief functions and Zadeh-Dubais-Prad theory of possibility. Graphically presented VBS is called valuation network.

**Figure 1.** The concept of evidential networks (Đapčić, M., Lukuić, Lj. & Pavlović, M., 2019)

VBS consists of set of variables and set of valuations that are defined on the subsets of these variables. Set of all variables is denoted by  $U$  and represents a space covered with problem which is under consideration. Each variable represents a relevant aspect of a problem. For each variable  $X_i$  will be used  $\Theta X_i$  to denote the set of possible values of

variables called the frame of  $X_i$ . For a subset  $A$  ( $|A| > 1$ ) of  $U$ , set of valuations that are defined over  $\Theta A$  represents the relationship between variables in  $A$ . Frame  $\Theta A$  is a direct (Cartesian) product of all  $\Theta X_i$  for  $X_i$  in  $A$ . The elements  $\Theta A$  are called configurations of  $A$ .

Knowledge presented in this type of valuations is called generic or general knowledge (Fig. 1), which can be represented as a knowledge base in expert systems.

The VBS also defines valuations on individual variables, which represents so-called factual knowledge, and it constitutes database in expert systems (Figure 1). For a problem, general-generic knowledge defines an expert. During reasoning process that knowledge won't be modified. Factual knowledge will vary in accordance with condition of a problem currently being under consideration. The VBS treats on the same way these two kinds of knowledge.

The VBS systems suited for processing uncertain knowledge described by functions of belief function theory are called Evidential Reasoning Systems or Evidential Systems, and valuation networks are now called evidential networks (EN) (Figure 1).

The objective of reasoning based on the evidence is an assessment of a hypothesis, in case when the actual evidence is given (the facts). This can be accomplished by evaluating valuation networks in two steps (Đapić, M., Lukuić, Lj. & Pavlović, M., 2019): Combining all belief functions in evidential network, resulting in a so-called global belief function; Marginalization of global belief functions in the framework of each individual variable or subsets of variables produces marginalized values for each variable or subset of variables.

Easily way of understanding the reasoning process and its graphical interpretation is the condition on which depends whether and how fast these systems will be applied in solving everyday problems. As a software support to the VBS systems application, several software tools have been developed. For evidential systems the very known are: McEvidance, Pulcinella and DELIEF. McEvidance is an application that was developed for reasoning under conditions of

uncertainty (Figure 3). Using this system the user can create a graphical network of variables, their relationship and to bring in any records related to the variables. When all available input records that reflect current system status or process under analysis are being entered, evaluation of network can start.

During evaluation process first the global belief function is being generated by applying combining operation and then afterwards the marginalized values of all variables are being calculated.

### 3. Flexibility of Routing in DFMC

Flexibility is defined as the ability of a technological system to cope with variable circumstances (Buzacott, J. A., & Mandelbaum, M., 1985) or instability caused by the environment (Mascarenhas B., 1981). Flexibility is one of the key objectives of any technological system and a critical measure of overall production performance.

From the theoretical postulations of the characteristics of FMC according to Lim (1986) and Yilmaz and Davis (1984), flexibility is determined by eight categories of flexibility: Machine Flexibility, Process Flexibility, Product Flexibility, Routing Flexibility, Volume Flexibility, Process Sequence Flexibility, and Production Flexibility.

Routing flexibility can be defined as the ability of a technological system to cope with failures and continue producing a given set of parts. This ability exists if a particular type of part can be processed through several routes, or equivalently, if each operation can be performed on multiple machines. The main applicable circumstances arise when a system component, such as a machine tool, breaks down. This flexibility can be measured by the robustness of the FMS when there are failures, and production continues in changed circumstances. This

flexibility can be achieved by allowing automated and automatic redirection of parts to other machines, which also enables redundancy of machine tools; as well as duplicating the assignment of operations.

Monitoring systems or tracking networks can be a powerful tool in determining routing flexibility, i.e., determining the optimal grouping of parts for processing in a didactic flexible cell (DFMC). By varying different geometric shapes that can be found in the educational process, i.e., students' exercises, the characteristics of DFMC that we want to present to students can be emphasized.

In the example we are analyzing, we want to examine Routing Flexibility for two given conceptual solutions of DFMC.

Routing flexibility in FMC refers to the ability of the production process to change depending on production needs. This flexibility allows production processes to be optimized for different types of products, reduce waiting times, and increase overall productivity. Specifically, as previously mentioned, routing flexibility allows FMC to adapt to different production tasks and changes in production without the need for manual intervention. For example, if a machine breaks down or there is a production interruption, routing flexibility allows the production process to be redirected to other machines in the FMC to avoid loss of time and resources. Additionally, routing flexibility allows FMC to adapt to different production quantities and needs. Calculating routing flexibility for FMC usually involves analyzing different possible routes through the manufacturing system, taking into account various factors such as machine availability, production time, maintenance needs, and the like.

One way to calculate routing flexibility in FMC is to use production process optimization algorithms. These algorithms consider various optimization criteria such as production time, production costs, or

maximizing production capacity. Another way to calculate routing flexibility in FMC is to use simulation modeling. Simulation modeling allows for the analysis of different production scenarios, taking into account different conditions and parameters, in order to assess the performance and flexibility of the FMC.

In both cases, calculating routing flexibility in FMC is a complex process that depends on many factors and requires expertise and experience in manufacturing engineering and automation.

The available example being analyzed involves two concepts of DFMC. The common characteristic of both DFMCs relates to the following identical components: a robot with a peripheral axis, a CNC milling machine, programmable and gravitational feeders, and a type of control system (robot controller and machine control unit). The difference relates to the CNC lathe. The first DFMC has a standard (classical) type of turret head, and the designation DFMC1 is introduced for this flexible cell. The second flexible cell has a turret head with driven tools that allow the CNC lathe to perform smaller milling operations, which gives it the ability to process parts from group two according to the part categorization in Table 2 on a single type of machine; i.e., a CNC turning center. The designation DFMC2 is introduced for this type of flexible cell in further analysis.

In the analysis of Routing Flexibility, evidence systems for the established part groupings have two clear goals. The first concerns the display of the ability of evidence networks to absorb knowledge that has been accumulated over the years in production engineering. The second goal relates to the expansion of previously generated evidence networks and their use as an auxiliary tool in the decision-making process. These goals will be achieved through an example that relates to the selection of part structures for processing a

hypothetical group. This type of part has already been used in other types of exercises (e.g., designing a technological process for CNC machines), so students have some experience.

As a result of the analysis, different classes of surfaces were identified on all parts (Figure 1). Types of processed surfaces include primary rotational (PR), secondary planar external (SPo), secondary planar internal (SPi), primary planar (PP),

secondary rotational (SR), etc.

Primary surfaces give parts their general shape. Secondary surfaces, such as planar internal and external surfaces and auxiliary holes, are processed from primary surfaces. The division of surfaces into primary and secondary was not made based on functional importance or processing complexity. Based on the classification of hypothetical surfaces, parts are divided into five categories, as shown in Table 1.

**Figure 2.** Different classes of surfaces

The classification of all parts into five categories was based on the combination of these surfaces, and is shown in Table 1. Accordingly, using the corresponding statistical analyses in Table 2, we form the percentage of the use of different processing machines or types of mechanical operations for processing each category of parts. These percentage ratios are also valid for the total number of operations for final processing. Thus, in the first category of parts, 100% of the work is represented by groove milling, while in the second category of parts, 75% is attributed to milling and 25% to drilling.

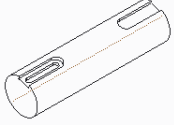

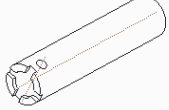

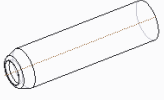

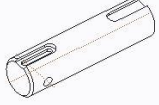

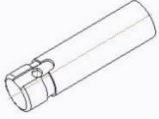

It is important to note that the level of reliability of the data in Table 2 cannot be taken as 100%. By default, in the following analysis, we will assume that the level of reliability in the accuracy of this data is 95%. This means that the results of the analysis

that was prepared (in the case considered by the lecturer) can be considered accurate with a probability of 0.95.

The rest of this paper shows how to apply the generated knowledge in conceptual design. The theory of belief functions together with proof systems or evidential networks allowed for the presentation of this knowledge in an appropriate form and later use as an aid in the decision-making process.

The group of lecturers analyzed their exercise program and decided to adapt it to students in such a way that the flexibility of routing in DFMC is better demonstrated by choosing an adequate group of parts. The percentage share of these parts with corresponding belief functions is shown in Table 3 for one of the variations presented in Table 5.

**Table 1.** Categorization of parts in school examples of exercises

	Categorization of parts in school examples of exercises	Example sketch
1.	Secondary Planar In (SPi)	
2.	Secondary Planar Out + Secondary Rotational (SPi+SR)	
3.	Secondary Rotational Out + Secondary Planar In (SRo+SPi)	
4.	Secondary Rotational Out + Secondary Planar In + Secondary Rotational (SRo+SPi+SR)	
5.	Secondary Rotational Out+ Secondary Rotational In + Secondary Planar In + Secondary Rotational (Sro+SRi+SPi+SR)	

**Table 2.** The percentage share from total assumed work for each operation of machining divided into categories of parts

Machining operations	Parts Category				
	SPi	SPi+SR	Sro+ SPi	SRo+Spi+SR	Sro+SRi+Spi+SR
Milling	100%	75%	30%	70%	55%
Turning			70%	15%	35%
Drilling		25%		15%	10%

**Table 3.** The number of parts in the series

The number of parts in the series			
Serial number	Type of work	Quantity	%
1	SPi	1	10
2	SPi+SR	1	10
3	SRo+ SPi	2	20
4	SRo+SPi+SR	2	20
5	Sro+SRi+SPi+SR	4	40

If we analyze the flexibility of routing for five different parts from Table 1, the percentage unit flexibility of routing for a specific processing strategy can be determined through artificial intelligence software (OpenAI., 2021). Based on the following facts:

- The flexible cell DFMC1, which has components: CNC lathe, CNC milling machine, robot with slider,
- Processing five different parts; the first has a milling operation, the second has a drilling and milling operation that is performed on a milling machine, the

- third has a double turning operation on DFMC1 or turning and milling on DFMC1, the fourth has milling and drilling on the milling machine DFMC1, and the fifth has turning, milling, and drilling on DFMC1, where milling and drilling are performed on the milling machine,
- Unit quantity of parts per group (first piece 1, second piece 1, third piece 1, fourth piece 1, and fifth piece 1), and
  - asking the artificial intelligence the question: "What is the percentage flexibility of routing for milling operations on FMC1?" The answer received is:
  - The percentage flexibility of routing for milling operations on FMC1 is given by the formula:
  - Percentage flexibility of routing = (Number of possible routings / Total number of operations) \* 100%

- Total number of operations: Total number of operations = Number of operations for the first part + Number of operations for the second part + Number of operations for the third part + Number of operations for the fourth part + Number of operations for the fifth part  
 Total number of operations = 1 + 2 + 2 + 2 + 3  
 Total number of operations = 10
- For routing milling operations, there are three possible paths for operations on FMC1 (CNC milling machine). These operations can be performed on the first part, second part, and fourth part. Therefore, the number of possible routings is 3.
- Percentage flexibility of routing for milling operations on DFMC1 = (3 / 10) \* 100% = 30% Therefore, the percentage flexibility of routing for milling operations on FMC1 is 30%.

Similar questions and answers obtained from the software are presented in Table 4.

**Table 4.** Percentage flexibility of routing for operations

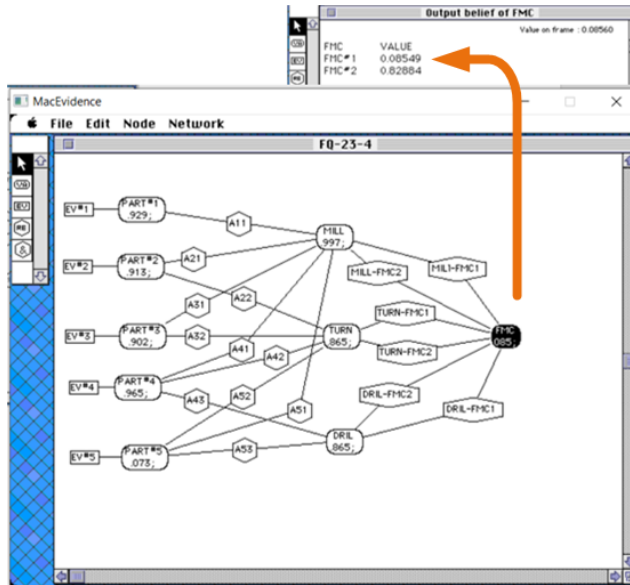

Percentage flexibility of routing for operations	Type DFMC	
	DFMC1 [%]	DFMC2 [%]
Percentage flexibility of routing for milling operations	30%	60%
Percentage flexibility of routing for drilling operations	20%	50%
Percentage flexibility of routing for turning operations	20%	67%

On the base of previous explained modeling knowledge with belief function of Dempster-Shafer theory is possible to create appropriate evidence network (Figure 3).

flexibility for DFMC1 and the highest routing flexibility for DFMC2 are evident. For the group of parts consisting of 10% of parts from the first group, 10% of parts from the second group, 20% of parts from the third group, 20% of parts from the fourth group, and 40% of parts from the fifth group, it can be concluded that it has average routing flexibility values compared to the analyzed groups of parts DFMC1 and DFMC2 (DFMC1=0.0857 and DFMC2=0.8273).

Table 5. shows data indicating a change in beliefs about routing flexibility depending on the percentage content of individual groups of parts. It is evident that all groups of parts processed on DFMC2 have incomparably greater routing flexibility compared to DFMC1. Thus, the group of parts consisting of 30% of parts from the first group, 30% of parts from the second group, and 40% of parts from the fourth group has the highest routing flexibility for flexible cell DFMC1, and the lowest routing flexibility for DFMC2. For the group of parts consisting only of parts from the first and fifth classes (DFMC1=0.0752 and DFMC2=0.8637), the lowest routing.

**Figure 3.** Evidence network with output belief

**Table 5.** Distribution of beliefs regarding routing flexibility

of group	Partial participation of the first, second, third, fourth and fifth categories in the group															Distribution of beliefs		
	I. SPi		II. SPi+SR		III. Sro+ SPi			IV. SRo+Spi+SR			V. Sro+SRI+Spi+SR			Bel (DFMC)

## 4. Conclusion

FMC (Flexible Manufacturing Cell) is a manufacturing system that consists of flexible machines and equipment organized in a manufacturing cell. This system allows production to quickly adapt to changes in order to avoid production downtime. Didactic FMC (DFMC) system is typically a smaller and simpler manufacturing system used for educational purposes to provide students with practical experience in production. In this sense, the analysis of the routing flexibility of the didactic FMC is conducted in the technological system design phase, but the objectives of this analysis are different than those of real manufacturing systems.

In DFMC, the objective of routing flexibility analysis is to evaluate the system's efficiency in producing different products, as well as the system's ability to adapt to changes in the production program. This analysis is usually conducted to improve the performance of the didactic FMC and enable students to learn the basic concepts of production and production processes.

On the other hand, in real manufacturing systems, the objective of routing flexibility analysis is to improve production efficiency and increase the competitiveness of the company in the market. This analysis is usually conducted to improve the manufacturing system's ability to adapt to changes in the production program and market demand, as well as to minimize

production costs.

In summary, although routing flexibility analysis is conducted in both types of FMCs, the objectives of the analysis and the way in which the results are applied are different.

In order to improve the quality of the teaching process, it is useful to find an adequate configuration of the group of parts intended for processing on the DFMC, which will adequately and clearly present a certain characteristic of the flexible system. In the presented example, one of the characteristics of FMCs, including DMFCs, is routing flexibility. Routing flexibility analysis as well as decision-making regarding routing flexibility can be successfully realized by applying the theory of belief functions - Dempster-Shafer theory and evidence nets developed on the basis of this theory.

In the exercise preparation phases, decisions are made about geometric, technological, kinematic, and flexible characteristics (routing flexibility) under conditions where there is no reliable knowledge about which parts, what configurations, and which technological processes will be used to process workpieces on CNC machines. In the formation of these decisions, artificial intelligence software and the theory of belief functions (Dempster-Shafer) play a crucial role. Proposed software solutions have successfully replaced expert knowledge used in the decision-making process, and the results obtained have justified the comprehensive benefits of this methodology

## AI APPLICATION IN QUALITY ASSURANCE OF INDUSTRIAL LASER WELDING PROCESSES

**Abstract:** *The purpose of this paper is to explore conventional laser welding quality control methods and compare them with modern AI-based (Artificial Intelligence) testing solutions, highlighting the potential of AI in laser welding quality assurance. AI can effectively monitor various laser welding process signals and parameters to determine weld quality. Furthermore, AI image recognition can enhance weld error detection precision when monitoring laser welding with vision systems. In cases where conventional quality control methods, such as X-ray, are utilized, AI can be employed to process and interpret test results, reducing the time and effort required for a human operator. This paper presents and briefly discusses several successful AI application examples in laser welding quality assurance, as well as application possibilities, demonstrating the latest state-of-the-art non-destructive laser welding test solutions.*

**Keywords:** *Artificial Intelligence, Laser Welding, Quality Assurance, Non-Destructive Testing*

### 1. Introduction

Achieving a certain quality standard requires taking into consideration several factors – technical, technological, and economic[1]. Working conditions and equipment, production layout, as well as expenses of inspection, testing, and rework all affect the quality of the product. [2] The same criteria can be applied to the assessment of the quality of welded joints. However, when it comes to welding it is crucial to control and monitor the entire process, as errors can be frequent and consequences can turn out to be severe and costly [2].

The advent and improvement of artificial intelligence (AI) and its subfields, resulted in their rising impact on the manufacturing industry [3]. The advantages automated procedures hold over manual work increased

the popularity of AI applications in manufacturing processes, especially quality control [3]. The implementation of machine learning (ML) models in industrial quality has proven to be of great use as it contributes to savings in resources, time, and money. A few examples of applied ML models in quality inspection procedures are stated hereinafter[4].

Faults and defects in laser welding evaluated during quality control can be classified either as internal or external [2]. External defects can be detected by the naked eye or with magnifying glasses, as they appear on the surface of the material [2]. Internal defects can only be detected after the metallographic preparation of the samples [2]. These defects occur under the surface of the material. Some of the most common welding discontinuities are:

---

<sup>1</sup> Corresponding author: Nemanja Pajić  
Email: [pajicnemanja2@gmail.com](mailto:pajicnemanja2@gmail.com)

- cracks,
- cavities,
- solid inclusions,
- lack of fusion and penetration,
- impering shape and dimension.

Welding parameters should be closely followed during process as they affect the quality of the weld [19]. For example, by analyzing and controlling parameters such as the laser power, the welding speed, and the size of the laser beam, the formation of welding discontinuities can be predicted [12]. Also, process parameters determine the geometry of the keyhole which affects the weld geometry and quality[5].

### **1.1 AI application in industrial quality**

AI-based methods are most commonly used for prediction, classifying a large amount of obtained data, and in optical inspection, when a high level of precision and accuracy is required for time-consuming and monotonous work.

An example of optical inspection based on a machine learning method is a blister defect detection for polymer lithium-ion batteries (PLB) performed by Ma et al. [6]. In this case, a widely used deep learning model, convolutional neural network (CNN), is employed to detect blisters in PLB sheets from images [4]. This can be regarded to as an image classification problem[6]. CNN uses a hierarchical structure to gradually extract advanced features from low-level features. It then uses these advanced features to do image classification and detect defects in PLB sheets from images [6].

Further use of machine learning methods is found in the identification of root causes of failures and quality deviations. Lokrantz et.al.[7] uses a Bayesian network, a form of a probabilistic graphical model, to represent dependence between manufacturing stages. This model uses expert knowledge and previously recorded data to perform

inferences regarding the root causes of quality deviations [7]. Such framework provides a chance for the knowledge to be stored for further use and distributed to other manufacturing sites [7].

Another instance of employing machine learning tools is set by Sumesh et. al.[8]. They used two different classifier algorithms, J48 and Random Forest, to determine the quality of the weld based on the corresponding arc sound [7]. Input parameters for the classifier were sound signals recorded during experiments and later generated in Matlab software. The accuracy Random Forest showed was 88.69% and that of J48 was 70.78% [7]. Although the results turned out to be satisfactory there is still room for enhancing the performance of algorithms by bettering the conditions in which the sound arc is recorded, according to Sumesh et al. [7].

### **1.2 Conventional laser welding quality controls**

Laser technology has been present in the industry for more than 40 years, and it has contributed greatly to the improvement of welding efficiency and accuracy [9]. These developments enable greater manufacturing flexibility (control over design) and therefore increase the range of useful material properties that can be achieved [8]. However, laser welding requires rigorous control and constant process monitoring to achieve a high-quality standard [2]. Conventional methods used to evaluate the quality of a welded joint can be destructive or non-destructive [1].

Destructive tests are achieved through mechanical and structural tests and they provide quantitative indicators of the quality of the welded joint [2]. To determine the mechanical properties of welded joints, it is necessary to make test samples under the appropriate standard [1]. These samples are obtained by cutting a small part of the

welded piece that was intentionally left there, or by making special pieces (test plates) that are welded using the same procedure and welders as the planned construction [10]. Some mechanical tests include testing by tension, bending, measurement of hardness, etc [10].

**Figure 1.** Test plate

To determine the structure of the welded joint, structural (metallographic) tests are performed [10]. Samples used for these tests are prepared by grinding and polishing, after which the surface of the sample is etched [9]. The choice of the chemical reagent used for etching is based on the material of the tested object [10]. This procedure lets us see the macroscopic appearance of the welded joint as well as the microstructure in the thinned zones of the welded joint [10].

On the other hand, non-destructive evaluation involves the detection and assessment of deviations on both the surface and interior of the material [2]. Considering the fact that achieving a welded joint without any discontinuities is almost impossible, it is important to determine their shape and dimensions [1]. Discontinuities aren't considered errors if they are evaluated to be

within the permitted limits, prescribed in the quality requirements of the welded joint [1]. During these tests, the material is not damaged in any way. Some of the most common non-destructive tests are visual tests, testing with liquid penetrants, magnetic flux testing, ultrasound testing, and radiographic examination [10].

Both destructive and non-destructive methods usually require a lot of time and additional workstations, specialized equipment and materials, and trained staff, resulting in a high cost [11].

## 2. Smart laser welding quality assurance systems

An alternative to conventional quality assessment methods is found in the development and integration of process monitoring systems. These systems detect welding errors during the process and the negative impact of uncertain interfering factors can be effectively reduced and flawed parts can be separated [11].

When it comes to laser welding, process monitoring is conducted in three stages. In the first stage, during the pre-process, the weld seam is tracked [12]. After that, the melt pool, weld defects, spatter, etc. are monitored during the process. Lastly, the geometry of the weld and visible defects are examined post-process [12].

Using AI-based methods, weld features, defects, and the state of the weld can be predicted and adjusted [13]. Also, corrective measures are proposed through feedback to system control if needed, and the entire process becomes more efficient over time, as more data is collected. There are different methods used for process monitoring and quality assessment.

### 2.1 Signal monitoring sensor techniques

During process monitoring, the most commonly monitored signals are acoustic, optical, and thermal.

**Acoustic emission signal** is one way to monitor the laser welding process. The plasma ejected from the keyhole leads to pressure fluctuations which bring about the acoustic signal [13]. This signal can be measured without contact, by using a microphone or a resonant sensor [14].

Acoustic signatures, such as sound pressure deviation and band power, can be used to specify the weld penetration by applying a neural network algorithm and regression analysis methods [15]. The algorithms effectively separated full penetration from partial penetration. An automatic measure and control system designed by Lv et al. [16] proved that acoustic signals are also helpful in controlling arc length in real-time, based on the linear relationship between the arc sound and arc length. The linear fitting model was used to predict the surface height of the molten pool. Achieved prediction results were successful [16].

The main downside of this signal is its susceptibility to environmental noise. This interferes with the forthputting of acoustic signal monitoring[13]. However, this can be avoided by using noise reduction methods to reduce the background noise signals [17] or by using a plane microphone array system, composed of eight microphones [18].

**Optical signal** monitoring consists of optical radiation and optical vision monitoring [13]. The molten pool, spatters, and plasma emit strong optical radiation, and the optical radiation signal mainly comes from the laser beam and the welding area [19]. Based on a different wavelength, optical radiation signals can be divided into two categories – one is UV and VIS radiation, where the wavelength is 0.3 – 0.7  $\mu\text{m}$ , and the other is IR radiation with a wavelength range

between 1.1  $\mu\text{m}$  and 1.6  $\mu\text{m}$  [20, p.]. The equipment used to collect the optical radiation signals consists of, most commonly, spectrometers, photodiode sensors, high-speed cameras, CCD cameras, and CMOS cameras [13]. This monitoring method is widely used nowadays as it provides a large amount of reliable data. For example, [21] used the image processing method under different welding conditions to gain insight into the dynamic behaviors of the keyhole, and [22] measured the velocity and direction of the fluid flow inside the keyhole, by attaching a glass plate, very precisely. Results showed a connection between the fluid flow and laser power, feed rate, and welding gap [22]. Still, due to spatial restrictions, the signal camera sensor is limited in data collection[13]. To avoid this downside and to be able to extract enough features for proper evaluation of the quality of the weld seam, researchers opt for multiple camera sensors [13]. This way, the welding zone can be monitored from different angles and extensive information can be obtained [13].

**Thermal radiation signal** is especially strong in the keyhole, the molten pool, and the high-temperature metallic vapor, as the temperature and thermal radiation are very high in these parts of the welding zone [13]. Frequently used sensors for obtaining thermal signals are pyrometers and IR cameras [13]. While the pyrometer is cheaper and easier to assemble, the IR camera can reflect the temperature distribution of the welding zone more extensively [13]. IR images of the molten pool were used to estimate the width and depth of the weld seam[23], [24]. By analyzing the emitted thermal radiation, Weberpals et al. [25], examined the temperature distribution and geometrical structure of the welding zone. This approach could also be used to define the inclination of the keyhole [25].

## 2.2 Monitoring techniques

**Traditional monitoring methods** can be divided into two approaches, coaxial and paraxial [26]. The coaxial monitoring method monitors the welding zone by installing a spectroscope in the laser propagation path. [27]. Obtained optical and thermal signals are stable and undisturbed. The imperfection of this method is its lack of flexibility and complex installation of the monitoring sensor [13]. However, paraxial monitoring is characterized by easily adjusted monitoring distance and angle between the welding zone and the sensor [13]. These traditional methods commonly represent a basis for novel monitoring methods and multi-sensor fusion technology [13].

**Novel monitoring methods**, like X-ray imaging technique, inline coherent imaging (ICI), magneto-optical imaging (MOI), etc. have achieved good results in obtaining some welding features, which are normally difficult to get during the process [13]. These features, like the depth of a keyhole for example, are very helpful when evaluating welding quality since they are closely connected to it [13].

**X-ray videography** can obtain temporally and spatially defined information about the keyhole geometry during the welding process[5]. Furthermore, this method can also be used to identify the inner defects of the weld seam with high spatial and temporal resolution [13]. By using an X-ray diffraction system, the microstructure and mechanical properties of the weld seam can be investigated [28], and residual stress distribution in the weld seam measured [29].

**Optical coherence tomography (OCT)** is another novel technique. OCT is a 3D measuring technology for automated laser welding[13]. It can serve as a basis for an inline monitoring device used to extract the tomographical geometrical measurement

data during the process of weld seam forming [30].

**The MOI technique** is based on the magnetic induction principle and the Faraday rotation effect [31]. An experiment showed that the microstructure of the weld joint can be investigated using the MOI method, and without the metallographic preparation process [32].

Automated monitoring of laser welding processes is often achieved using *weld watchers*. Analyzing the measured light emission, created from the interaction between the laser and the material, weld watchers can recognize errors in welding based on previously recorded error-free weldings[33] [32].

Figure 2. Weld watcher

Using smart evaluation methods, weld watchers can signal warning thresholds to the system control completely automatically [32].

**Multi-sensor fusion technology** combines various signal sensors and benefits from the advantages of each one [12]. It can, therefore, monitor the welding process effectively and comprehensively [13]. The main sensor of this technology is usually the vision sensor, as it provides extensive information about the welding zone [13]. The combination of sensors varies based on the desired outcome. For example, the X-ray system can be combined with the high-speed camera [34], the sound sensor with the vision sensor [35], etc.

### 3. Successful examples and possibilities of AI application in laser welding quality assurance

AI can be applied in many ways to ensure the quality of the welded seams, significantly reducing test costs, especially compared to destructive test methods. Possibilities are numerous, but some of the most significant would-be AI monitoring of various process parameters to determine weld quality, monitoring optical signals during welding and applying AI image recognition, and AI result processing and interpretation for some of the conventional control methods (such as X-Ray). A few successful application examples shall be presented and shortly discussed.

**Image recognition** can be applied in many ways in quality control of welded joints. Welding errors can be detected while observing the melt pool contour, (melt-on and the resolidification line) [11]. Various defects can be identified in this way, especially lack of fusion. In order to have a proper setup researchers have used a CMOS camera with an additional light source, and a robust algorithm for image analysis. Image recognition approach can be utilized to detect laser optical backlash during welding, a heat camera can be used to monitor thermal distribution patterns, or different light sources can be applied in order to have a visual inspection of the welded seam in form of a machine vision [6], [11], [19], [23].

**Monitoring process parameters** in order to determine weld quality can be a very promising approach. Non-visual process parameters could be monitored during the welding process. For example, AI can be trained to monitor temperature, voltage, electric current, sound, pressure, and many other parameters during welding and determine the outcome of the welding operation based on various combinations of

parameter values [8], [11], [13], [35]. When possible, the most economical approach is to use existing process parameters measurement values, without investment in microphones or other measurement devices. An example of this approach is the utilization of an adaptive neuro-fuzzy inference system (ANFIS) and multi-gene genetic programming (MGGP) to predict the laser weld quality, such as surface roughness, weld strength and more [36].

**AI result processing and interpretation** is a useful method to eliminate long manual work, make the process cost-efficient, and get the testing results faster. Eddy current testing, ultrasonic testing, X-Ray, or CT (computer tomography) scanning can provide as an output a very complex result. For a human, it can be quite tricky to analyze, understand and interpret those results, and the process can take a long time. If a CT scan of a laser welded seam is analyzed for pores, on the output scan an operator should look for pores, measure them and make a report. Many scanning systems have a built-in AI feature for porosity analysis, but if porosity-induced fatigue damage should be calculated numerous calculations should be performed. Researchers have tried to predict porosity-induced fatigue damage of laser welded joints, where the AI algorithm could be a very beneficial tool to increase prediction accuracy and reduce testing time [37], [38].

### 4. Conclusion

This paper provides a rough overview of the AI application in industrial quality, with a focus on laser welding quality assurance. Basics of the laser welding process were given, followed by conventional laser welding control methods. Conventional testing methods can be quite costly and time-consuming, especially destructive testing methods. State-of-the-art technologies

provide better solutions. AI prediction models or process monitoring solutions can be applied to provide real-time test results in a high-speed production environment with very low investments, and very low testing costs.

Through various examples of AI application in laser welding quality assurance, it is shown that there is a great potential to improve conventional quality control systems, shorten the test duration, reduce the test cost, improve defect detection precision, and much more. AI can be successfully

applied to monitor various laser welding process signals or parameters to determine the weld quality, in cases where laser welding is monitored with some vision systems AI image recognition can be applied to enhance the weld error detection precision, or if a conventional quality control method is applied (such as X-ray), AI can be utilized to process and interpret test results as it might be a time-consuming process for a human operator.

## STUDY ON OPEN CONTACT SYSTEMS WITH FLAT PARALLEL ELECTRODES FOR AERIAL ROBOTS CHARGING PLATFORMS

**Abstract:** *The authors of this paper proposed the design of a charging platform for aerial robots (ARs), the advantages of which are the simplicity of implementation, non-requirement of precision landing ARs on the platform and the possibility of servicing several robots simultaneously. The platform comprises a row of flat parallel open electrodes lying in the same plane and separated by thin dielectric spacers. One half of platform electrodes are connected with positive pole of the charging power source and another half – with negative one, and their polarities are interlaced. The AR has several on-board electrodes in its support stanchions, and their contact points are located at the vertices of a regular polygon. Geometric analysis of the on-board electrodes' positions on the platform has been carried out. Practical recommendations have been given for configuring electrodes that can lead to 100% probability of correct contacting. Simulations with the help of the special software were carried out and the probability of correct contacting after landing for different number of contact points under uncertainty of their coordinates was estimated.*

**Keywords:** *Aerial Robot; Unmanned Aerial Vehicle; Landing; Charging Platform; Open Contact System.*

### 1. Introduction

The term “Aerial Robot” (AR) is used commonly in the field of robotics. It's been known for two decades, and it means a small pilotless flying machine with high degree of intelligence (Michelson, 1998). The better known term is “Unmanned Aerial Vehicle” (UAV) which has long been used in aviation. An AR can be considered as an UAV “capable of sustained flight with no direct human control and able to perform a specific task” (Feron and Johnson, 2008). In other words, ARs is a big class of mobile robots based on UAVs for special tasks that can be

performed using their intelligence and autonomy.

There are many types of UAVs based on different flight principles (Liewet al., 2017). This paper deals primarily with the Rotary-Wing type of aerial vehicles (helicopters, multicopters) and other aircrafts (convertiplanes and other hybrids) capable of vertical take-off and landing (VTOL). VTOL UAVs are the closest to common notion of “robots” because of their capability of hovering, which has huge advantages, in comparison with Fixed-Wing aircrafts, for general versatility. Perhaps the most popular implementation of AR is the quadcopter due

to its successful combination of wealth of opportunities and ease of implementation (Ghazbi et al., 2016).

ARs are designed for various useful functions: aerial photography, monitoring, construction operations, agricultural works, delivery of small packages and so on. One of the most pressing tasks in aerial robotics is on-ground automatic service and maintenance of ARs. This is especially important for the operation of not one single AR, but their groups. Today many well-known companies, as well as new startups specializing in Unmanned Aerial Systems (UAS) (Austin, 2010), are developing various service stations for ARs (Aerobotics, 2022), (H3 Dynamics, 2022), (Noon.21st Century, 2022), (Skycharge, 2022), (WiBotic, 2022).

UAS comprises of one or more UAVs (ARs), along with the technical equipment necessary to operate them and other components (Fetisov, 2021). Full composition of UAS may be different depending on its purposes. UAS provides an infrastructure for working environment of ARs. Important components of UAS are service stations. These are specific objects of UAS infrastructure, mainly intended for refueling or recharging UAVs.

Commonly ARs' power units are fully electrical and on-board power supplies are accumulator batteries of Lithium Ion or Lithium Polymer types. Such batteries provide time duration about 30-40 min for helicopters or multicopters. This time is often not enough to carry out various tasks. The AR therefore must replenish somehow its on-board energy supply after discharging.

Different means are known for recharging on-board batteries of UAVs and thus providing long duration of AR's mission. Among them, for example, is transmission of energy to the flying UAV by laser beam (Cui et al., 2017). There are solutions for replenishing energy of on-board power

supplies by means of solar panels (Morton et al., 2015). Many various projects use electromagnetic field based wireless power transfer (Luet et al., 2018), (Nguyen et al., 2020), (Chittoor et al., 2021). But the most effective and the easiest way to implement recharging is periodical landing ARs onto a charging platform with special contact terminals fed by a ground-based DC power source.

A large number of technical solutions based on direct contact between on-board and surface electrodes are known. Many systems use various quick connectors with male plugs and sockets. Some of them have lock devices for reliability of contacting (Lee et al., 2016). One part of such connectors often have funnel-shaped centering housing with inside electrode for easy insertion of a corresponding protruding part with another electrode (Antonini et al., 2019).

Service stations may contain not only charging systems but also special automatic mechanisms for fast battery swapping. Such mechanism removes the discharged battery from the supported AR and replaces it with a freshly charged battery (Toksoz et al., 2011), (Swieringa et al., 2010). In this case, the AR will be held up at the station for the minimum time and the battery removed will be charged after AR's departure. In paper (Kemper et al., 2011) the comparison of simple charging stations with contact terminals of different types and the charging station with swapping of batteries is made. The authors proposed methodology for estimating the economic feasibility of automatic recharging/swapping stations for different applications.

Electrical connection between ground and on-board parts of charging circuit in many cases is worth using platforms with open contact systems (Kemper et al., 2011), (Al-Obaidi et al., 2020), (Fetisov et al., 2014). In this approach commutation of ground and on-board electrodes appears right after landing when AR's undercarriage open electrodes

touch and simply lay on ground platform open electrodes (pads, strips). Such solution, unlike the conception of charging stations with fixed plug-in connectors, provides arrangement of charging process even in conditions of inaccurate AR landing. There are no complex operations for connecting and disconnecting plugs after landing and before take-off. And, besides, one platform allows charging for a group of ARs simultaneously.

Typically, open surface electrodes lie in the same plane, but in some projects they are intentionally spaced at different altitudes, as in (Stoyanov, 2014), to facilitate the positioning of the vehicle on the platform and ensure the correct electrical connection between surface and on-board electrodes.

Redundancy of electrodes is used to enable independent positioning of the AR on the platform, with an excess of number of surface or on-board electrodes, or both of them. The number of electrodes exceeding the number of charging source poles, i.e. two, should be considered excess. Typically, the greater the redundancy, the greater the freedom to position the AR. And if there is no redundancy or its degree is small, then various additional positioning devices have to be used to ensure that the docking of the AR on the platform is correct (Galimov et al., 2020).

In this paper the authors present results of studying one type of platforms with open contact pads, namely so-called platforms with flat parallel electrodes (Fetisov and Akhmerov, 2019). Their main advantage is simplicity of implementation, and reliability is quite high if special requirements for geometric parameters of electrodes are met.

This article does not deal with short-range navigation and precision landing of the vehicle on the ground service platform. These tasks are usually performed by on-board and (or) land-based video cameras. Data fusion integrating video information

and signals from other sensors (inertial sensors, GPS receiver, barometer) is often used. These issues are relatively well covered in the technical literature (Saripalli et al., 2003), (Conte and Doherty, 2009), (Kendoul et al., 2009), (Kendoul, 2012), (Kong et al., 2013).

This work focuses mainly on the charging platform design and geometric analysis of the mutual positions of the AR's on-board electrodes and electrodes of the platform.

## 2. Charging stations based on landing platforms with flat parallel electrodes

The general idea of the proposed charging station (Fetisov et al., 2013) (Figure 1) uses redundancy of platform electrodes. It consists of a row of flat parallel electrodes implemented as metal stripes lying in the same plane and separated from each other by narrow insulating spacers. One half of platform electrodes are connected with positive pole of the charging power source and another half – with negative one, and their polarities are interlaced. Let's the AR has 4 on-board landing electrodes positioned at the end of the AR's legs. Due to special geometrical features of the platform and on-board electrodes different polarities of the on-board electrodes would be obtained under any position of the AR on the station. That is at least one on-board electrode would be of different polarity than others (condition of heteropolarity). The special on-board distributing diode circuit provides right connection of the on-board battery charging controller to the platform power source under any random combination of on-board electrodes' polarities (Figure 1, a). The charging controller is connected to the accumulator battery GB1.

If the width of the platform electrode is  $a$ , the width of the insulating spacer is  $\delta$ , and the length of the side of a square which vertices correspond to the contact points of

on-board electrodes is  $d$ , then the geometrical condition providing 100% probability of heteropolarity of on-board electrodes is the equality  $d=a+\delta$ . Due to the small size of  $\delta$  we shall count  $d=a$  (Figure 1, b).

Circuits of balancing battery cells and circuits of disconnection of on-board electronics during charging time are not shown in figure 1, a. Due to the special form of insulating spacers and ends of on-board landing electrodes short circuit between neighboring platform electrodes via a landing electrode is practically impossible.

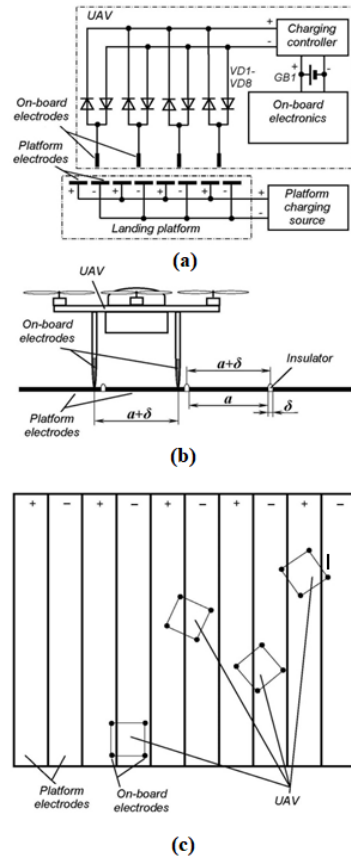

The described charging station may be used for service of a few ARs simultaneously (Figure 2).

### 3. Design of electrodes

For right positioning on-board electrodes on the ground platform and excluding situations when the on-board electrode lays on two adjacent platform electrodes simultaneously or gets stuck on the insulator's edge ends of on-board electrodes must be rather sharp (Figure 1, b). The contact area therefore is small. This fact makes it necessary to limit charging current and leads us to find a solution to improve reliability of contacting.

Improved contacting can be achieved in a number of ways:

- use of protective metal coatings,
- increasing the number of on-board electrodes,
- increasing the force of pressing on-board and ground electrodes together by the use of magnetic or electromagnetic elements (Mulgaonkar, 2012),
- providing conditions for all on-board electrodes to be pressed uniformly and qualitatively against strips of the platform.

**Figure 1.** Charging station with flat parallel electrodes: a – station structure; b – UAV positioning on the platform flat electrodes; c – random locations of on-board electrode contact points on the landing platform.

The latter can easily be achieved by spring-loading on-board electrodes. But it's not the only option. For example, figure 3 illustrates the technical solution in which an increase in the contact area is achieved by landing the AR on strips in the form of soft metal mats.

It is obvious that in case of landing on a soft strip its deformation thereof will contribute to "wrapping" the lower part of the tip with the deformed surface of the strip and to multiplying the contact area of the electrodes.

**Figure 2.** A charging station based on a platform with flat parallel electrodes can serve multiple ARs simultaneously.

**Figure 3.** The technical solution with spring-loaded electrodes and soft on-ground strips: 1 – rod of UAV landing gear (support stanchion), 2 – metal spring, 3 – metal tip (on-board landing electrode), 4 – dielectric separator, 5 – metallized coating, 6 – soft elastic material, 7 – current-carrying wire.

## 4. Geometric analysis of on-board electrodes possible positions

In the above example (Figure1), a UAV has four on-board landing electrodes. This case is typical of quadcopters, where it is convenient to place electrodes-stanchions under the motor-bearing beams of the device frame. In other cases, the number of on-board landing electrodes may also be chosen according to the number of bearing beams. For example, it is better to have three on-board landing electrodes for tricopter and six for hexacopter. And it is naturally to place contact points of them in the vertices of

regular polygons. Further we will examine in more detail some of the options for the location of the contact points. Only those variants of location are considered acceptable for which the probability of the ends of all electrodes falling onto strips of only one polarity is zero. That is, the situation of unipolarity for all contact points should be excluded.

### 4.1. Location of contact points at the vertices of a triangle

Of all geometric variants for triangles, only the position of the contact points on the vertices of a regular (equilateral) triangle is permissible. Figure 4 shows two near-critical but tolerable positions of contact points for this case. Still consider  $\delta$  negligible in comparison to  $a$ .

For the first variant shown in figure4 (length of side  $c_1 = a$ ), it is clear that, if the triangle is rotated, it is possible to make such a landing when all three touching points are on the same strip. For the second variant (the width of the strip  $a$  equals the height of the triangle:  $h = c_2 \cos 30^\circ$ ) such situation is excluded. At any rotations, one point of contact will lie on the adjacent strip relative to the other two. Therefore, it is better to select

$$c_2 = a / \cos 30^\circ \approx 1.155 \cdot a.$$

**Figure 4.** Near critical positions of the contact points at the vertices of regular triangles

A further lengthening of the side of the triangle is not permissible, as it is possible for two vertices on the base of the triangle to be on the same strip and for the opposite vertex to be on the strip «through one» (i.e. the polarity of all three vertices will be the same). For these reasons, touching points cannot be placed at the vertices of an unequal triangle.

Positioning the contact points of on-board electrodes at the vertices of the triangle has one clear advantage over all other possible variants (such as vertices of square, hexagon, octagon and so on): uniform pressurization of all on-board electrodes to the planes of the ground electrodes is guaranteed at all times, even if there are different irregularities, distortions and differences in the planes of the ground electrodes. For multicopters with four or more on-board electrodes, all electrodes have to be pressed uniformly by special measures (Figure3).

**4.2. Location of contact points at the vertices of a square**

This option has already been considered above. To meet the heteropolarity condition of on-board electrodes, it is necessary to maintain equality  $d=a$ , where  $d$  is the distance between adjacent contact points (the length of the side of a square). Positioning the contact points at the vertices of a rectangle is not acceptable, as all four of the on-board electrodes may be on strips with the same polarity.

Four landing electrodes can be found not only in quadcopters, but also in vehicles with higher number of rotors. For example, figure5 shows hexacopter and octocopter whose support stanchions are not made under each motor-bearing beam. At the ends of these stanchions, electrodes can be formed whose contact points fall into the vertices of the square.

**Figure 5.** Hexacopter and octocopter with four support stanchions

However, increasing the number of on-board electrodes can provide high charging currents. And from this point of view, the configuration of the on-board electrode system in which they are located under each beam of a multicopter at the vertices of regular polygons has some advantage. In addition, as will be shown below, configurations with high number of on-board electrodes provide a higher probability of successful landing that ensures the heteropolarity of on-board electrodes.

Then next consider the location of the contact points at the vertices of a regular hexagon (configuration for a hexacopter).

**4.3. Location of contact points at the vertices of a regular hexagon**

Similar to figure4, figure6 shows two near-critical but tolerable positions of contact points for this case. It is not difficult to see that the length of the side of the hexagon must be at least  $g_1$  (to prevent all vertices from falling into the same strip) and at most  $g_2$  (to prevent the opposite triads of the vertices from being through a strip from each other).

**Figure 6.** Near critical positions of the contact points at the vertices of regular hexagons

Simple geometric calculations yielded the following inequalities for the side of the hexagon  $g$ :

$$a/(2\cos 30^\circ) = 0.577a < g < a.$$

#### 4.4. Location of contact points at the vertices of a regular octagon

As in the previous case, consider two critical lengths of the polygon side ( $f_1$  and  $f_2$  shown in Figure 7). This length of the side of the octagon must be at least  $f_1$  (to prevent all vertices from falling into the same strip) and at most  $f_2$  (to prevent the opposite tetrads of the vertices from being through a strip from each other).

From simple geometric calculations we get the next double inequality for the side of the octagon  $f$ :

$$a \cdot \tan 22.5^\circ = 0.414a < f < a.$$

#### 4.5. Geometric analysis summary results

The results of the geometrical analysis that has been performed in 3.1–3.4 we placed in the summarizing table (Table 1). The optimal side lengths for regular polygons ( $c$ ,  $d$ ,  $g$ ,  $f$  for triangles, squares, hexagons and octagons respectively) with contact points at

their vertices are expressed by the strip width  $a$ . In addition, similar expressions are given for the circumcircle radius  $R$  for each polygon. This parameter is suitable for the simulation program described below. There is a known formula linking  $R$  to the length  $x$  of the side of a generalized regular polygon:  $R = x / (2 \sin(180^\circ/n))$ , where  $n$  is the number of sides of a regular polygon.

**Figure 7.** Near critical positions of the contact points at the vertices of regular octagons.

Column 4 of Table 1 contains expected optimums of the polygon side length and the circumcircle radius  $R$  at the fixed value of the strip width  $a = 200$  mm. This value will also be used later in simulations.

**Table 1.** Theoretically calculated optimal ratios\* between the geometry of the electrodes and the strip width  $a$

Number of on-board electrodes (Number of regular polygon sides)	Regular polygon side length symbol	The optimal length of the polygon side and the circumcircle radius $R$ expressed by the strip width $a$	Expected optimums of polygon side lengths, mm and the circumcircle radius $R$ , mm at $a = 200$ mm
3	$c$	$c = 1.155a$ $R = 0.667a$	$c = 231$ $R = 133.4$
4	$d$	$d = a$ $R = 0.707a$	$d = 200$ $R = 141.4$
6	$g$	$0.577a < g < a$ $0.577a < R < a$	$115.4 < g < 200$ $115.4 < R < 200$
8	$f$	$0.414a < f < a$ $0.541a < R < 1.307a$	$82.8 < f < 200$ $108.2 < R < 261.4$

\* Optimal geometrical conditions correspond to 100% probability of heteropolarity of on-board electrodes

## 5. Simulation Software

It is of practical interest how the probability of correct electrical connection of the on-board and ground parts of the charging system depends on the number of contact points, the size length of the corresponding regular polygon, and the uncertainty of the contact points' positions.

Estimating the probability of the correct position of the apparatus on the platform in an analytical form is rather problematic, so such estimation was made using the special software simulator, called CoptersLanding. The program allows to simulate random positions of the air robot on the platform, to analyze the polarity of contact points of the on-board electrodes and to calculate the percentage of successful and unsuccessful landings.

In Options Area of the program (Figure 8, on the right), the user can set the number of strips, length and width of strips, the number of on-board electrodes (contact points), the circumcircle radius for the regular polygon whose vertices coincide with contact points, and the uncertainty of the coordinates of the contact points (maximum random deviation of coordinates from given values). The user can set the single run or multiple runs of simulation.

The Results Area window of the program displays the result of the simulation (Figure 9, on the left). For all runs of simulation the polarity of each contact point is shown and the result of the landing - successful (I) or unsuccessful (O, in case of the same polarity for all contact points).

The final result is represented by the number of simulation runs and the percentage of

correct landings (Figure 9, the upper-left corner), which, if the number of runs is large enough, can be considered with some degree of approximation as a probability of successful landing.

The central part of the software window shows the view of the landing platform with strips of electrodes and images of all random landings represented as positions of contact points.

Only those landings for which all contact points of the UAV are placed on the platform without crossing its borders are evaluated.

The program allows to emulate simultaneously the AR random position on the platform and random deviations of coordinates of all contact points.

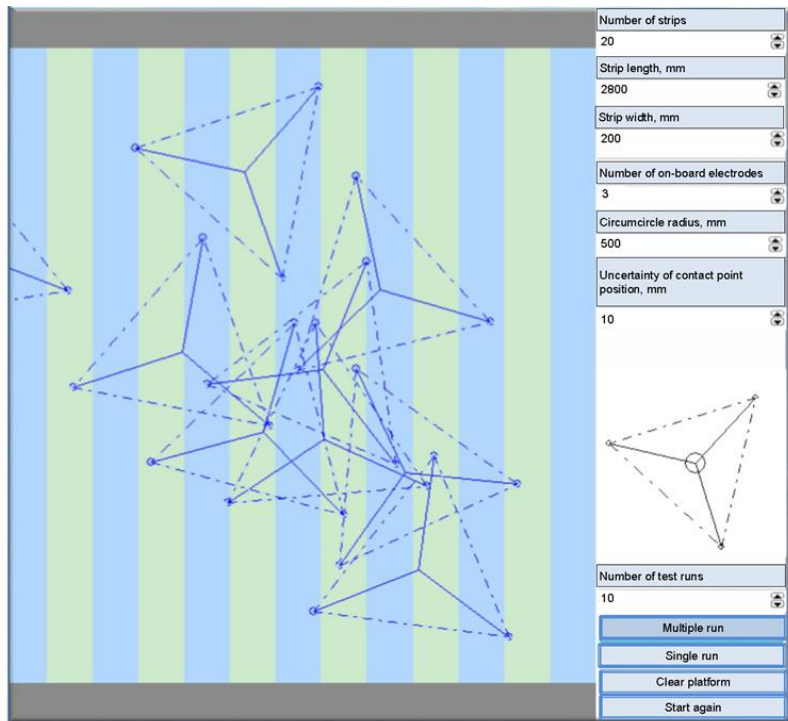

With a large number of statistical tests (in all simulations it was given at 10000), it is possible to get a reasonably reliable estimate of the probability of successful landings).

In all the evaluated cases of landings, the following geometrical parameters of the platform were given constant:

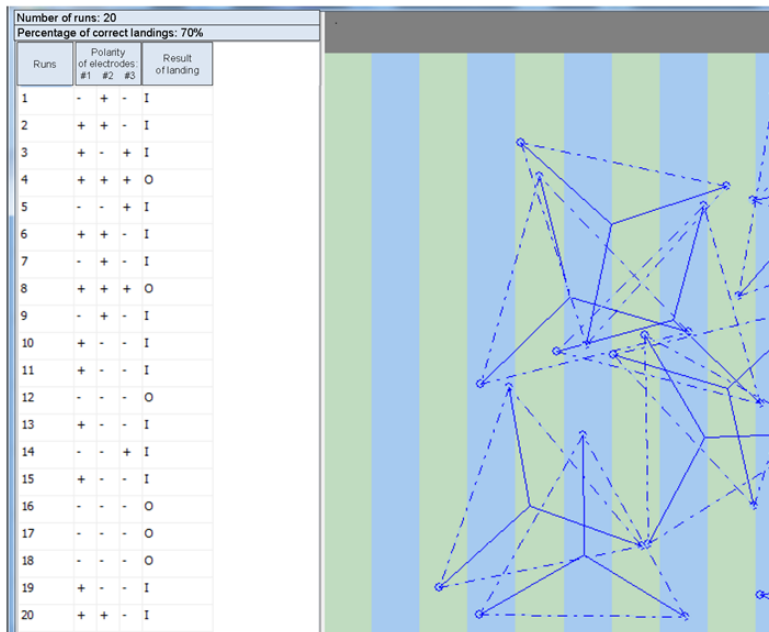

- number of strips: 20;
- strip length: 3000 mm;
- strip width: 200 mm.

The following parameters were varied:

- number of on-board electrodes: 3, 4, 6, 8;
- radius of the circumcircle: 50–400 mm;
- uncertainty of the contact points coordinates (limit values of random deviations with uniform probability distribution law): 0, 3, 5, 7, 10 mm.

**Figure 8.** CoptersLanding Options Area (on the right).

**Figure 9.** CoptersLanding Results Area (on the left).

6. Simulation results

Random landing simulation results for the case of the absolutely exact location of contact points at the vertices of regular polygons (the uncertainty of coordinates of

contact points  $\gamma=0$ ) are represented in the graphs of Figure 10.

The theoretical predictions shown in Table 1 have been fully confirmed by simulation results.

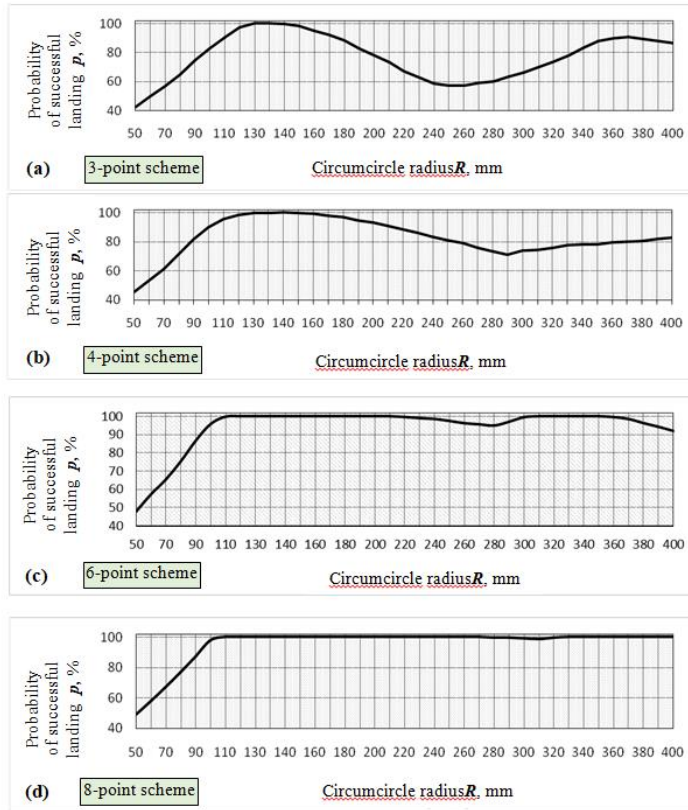

Figure 10. Probability of successful landing vs. circumcircle radius for different contact schemes: (a) 3-point scheme, (b) 4-point scheme, (c) 6-point scheme and (d) 8-point scheme

For all tested variants of the contact points' location (3, 4, 6, 8 points) there are optimal ranges of the AR's geometric parameters (radius of the circumcircle  $R$ ), at which the landing will always be successful in the sense of the correct commutation of electrodes. Furthermore, as can be seen from Figure 10(a – c), the optimality zone

expands as the number of contact points increases.

Somewhat unexpected was the presence of a zone of minimal probability of successful landing following the maximum zone (it is visible, with varying degrees, on each of the graphs of Figure 10(a – c)). Then again, the probability increases, though not always to 100%.

It would be difficult to predict theoretically the behaviour of the curve in this area. Therefore, a simulated computational experiment to assess the probability of a successful landing is practically the only reliable means.

A special series of simulations was implemented to estimate how the uncertainty of the contact points' coordinates  $\gamma$  affects the probability of successful landing  $p$ . Limit values of 0, 3, 5, 7, 10 mm were given successively for  $\gamma$ . These are typical values for real conditions, when the uncertainty of coordinates may be due to factors such as technological errors in the installation of the on-board electrodes or the inflexibility of the supports. The ranges of  $R$  within and in close proximity to the above-mentioned optimum zones were the most interesting to study. The behavior of the dependencies  $p = f(R)$  for the values  $\gamma = 0, 3, 5, 7, 10$  mm was studied in detail. The results for 3-, 4- and 6-point

contact schemes are presented in Figure 11-13.

The graphs show that for 3- and 4-point contact schemes where the optimal zone of  $R$  is relatively narrow, it is almost impossible to achieve a 100% successful landing at  $\gamma = 5$  mm and more.

For 6- and 8-point schemes (the graphs for 8-point scheme are not shown here, because they are similar to the graphs for 6-point scheme shown), starting with certain  $R$  values (in Figure 13, the values of  $R \approx 126$  mm), the uncertainty  $\gamma$  ceases to have any effect on the probability of successful landing.

The range of values of  $R$  where  $p = 100\%$  at any values of  $\gamma < 10$  mm continues to the right up to values about 260 mm for the 6-point contact scheme, and never ends at all for the 8-point contact scheme.

**Figure 11.** Probability of successful landing vs. circumcircle radius for 3-point contact scheme at different uncertainties of contact points' coordinates  $\gamma$

**Figure 12.** Probability of successful landing vs. circumcircle radius for 4-point contact scheme at different uncertainties of contact points' coordinates  $\gamma$

**Figure 13.** Probability of successful landing vs. circumcircle radius for 6-point contact scheme at different uncertainties of contact points' coordinates  $\gamma$

## 7. CONCLUSION

The developed simulation program made it possible to estimate the probability of successful landing of an aerial robot having regular arrangement of on-board electrodes (their contact points are located at the vertices of a regular polygon) on the charging platform that has flat parallel electrodes of interlaced polarity. Landing is considered successful if the condition of

heteropolarity for on-board electrodes is met, i.e. when in contact with strips, at least one on-board electrode shall have a polarity different from others.

The proposed methodology and tool can help to choose the right relationship between the geometrical parameters of the landing platform and the aerial robot.

In order to maximize the probability of a correct landing, it is necessary to observe the

special geometric relationship between the width of the ground electrode  $a$  and the distance between contact points of adjacent on-board electrodes (side length of a regular polygon), namely, according to Table 1:

- for 3-point contact scheme the distance between adjacent contact points must be  $1.155a$ ;
- for 4-point contact scheme the distance must be  $a$ ;
- for 6-point contact scheme the distance must be between  $0.577a$  and  $a$ ;
- for 8-point contact scheme the distance must be between  $0.414a$  and  $a$ .

Increasing the number of contact points extends the range of tolerable distances between adjacent of them when the probability of a correct landing is 100 %.

The latter conclusion is particularly important for conditions where contact points' coordinates are unstable. If, for example, random deviations of the contact points' coordinates are 5-10% of circumcircle radius  $R$ , it is impossible to reach 100% chance of a successful landing for 3-point and 4-point contact schemes (Figures 11, 12), but this is possible for 6-point and 8-point schemes, and the range of tolerable distances between adjacent contact points is rather wide.

## **AUTOMATIC TOOL PATH GENERATION IN CONTOUR MILLING USING GENETIC ALGORITHM**

***Abstract:** The purpose of this paper is to present new approach in automatic tool path generation in contour milling based on genetic algorithm and bitmap representation of work piece and additional resources. It deals with the problem of tool path generation and optimization in contour milling which is the most common case in metalworking industry. The starting point is assumption that the geometry of initial working piece, machined part and clamping fixtures is represented as bitmaps, then the mathematical model is presented and genetic algorithm is used to generate and optimize tool path. Proposed approach greatly reduced the costs of part production through improved machining efficiency, realized through independent software solution implemented in object-oriented language Delphi and can be used as starting point for fully autonomous NC code generation.*

***Keywords:** Genetic algorithm, optimization, milling tool path, bitmap representation*

### **1. Introduction**

The problem of tool path generation and optimization in chip removal machining processes has attracted the attention of a large number of researchers for several past decades. Machining in general and milling in particular is one of the main production processes used to manufacture durable goods. The cost optimization of production processes remains one of the major focus points of machine builders world-wide. (Khatiwada, Nepali, Raj and Bhattarai, 2020). The conventional ways of selecting the tool path or programming the NC code used data from machining handbooks and the knowledge of programmer for optimal processing (Bharath and Natraj, 2018). However, the conventional or traditional NC programming when compared to the modern CNC machining has many disadvantages for instance increasing time and cost production

and, decreasing accuracy and quality of the work piece. In the literature, there is a growing trend of development and application of models for the automatic generation and optimization of toolpaths. The most common and most researched approach is the application of artificial intelligence and metaheuristics algorithms in tool path optimization and milling processing parameter's selection, as well as the application of various geometry recognition techniques starting from a 3D model or from a 2D representation of the part. is reflected in the model setting and the modeling of goals and constraints.

Bharath and Natraj (2018) stated that determining the optimal machine tool path has been proven to lead to high productivity and minimal production costs. Furthermore, they provide statistical data related to the methods used by various authors in researches, with the conclusion that Genetic

Algorithms (GA) and Particle Swarm Optimization (PSO) method are largely used to optimize machining efficiency and when compared with other methods, the GA has been successfully applied for many optimization problems with various parameters related to tool path and effective in improving the robustness of feature selection over a range of problems.

Kumar and Khatak (2018) define the tool path as a sequence of positions within the surface to be machined and divide the surface into a grid with a finite number of squares, where each square represents one element of the tool path and the square is viewed as one point. The goal of optimization is minimization of processing time, minimization of the time required for tool change and positioning in high-speed motion, and minimization of the effect of jerk on the machined surface. The optimization is performed by applying the GA. Makhanov (1999) presents a mathematical model of a variable grid of points as a basis for path optimization in five-axis milling and provides an algorithm that generates a tool path consisting of different segments that are adapted to the type of tool movement and increases the processing accuracy. Jacso, Matiasi and Szalay (2019), presented the model of tool path generation in contour milling, which is not based on the discretization of the surface being processed, but on equations from analytical geometry and vector calculus, which assumes that the angle of engagement of the tool is always constant. The generated tool path follows the shape of the contour, that is, it enables the processing of any shape of the contour, but the model does not foresee path optimization.

The model that integrates toolpath generation and optimization is provided in the research of Barclay, Dhokia, Nassehi (2015) The model is based on the discretization or pixelization of the surface, which is processed by levels, that is, the tool

path is generated and optimized for the value of the axial depth of cut. The authors state that the problem of path generation in milling can be viewed as a TSP problem (Traveling Salesman Problem) that can be efficiently solved by applying GA. Like Kumar and Khatak (2018) the surface to be processed is modelled with a mesh with a finite number of squares, where each square represents a tool positioning point, i.e. a city through which a traveling salesman must pass, establishing an analogy with the TSP problem. They define the number of squares in the grid as finite, limited only by the resolution of the CNC machine. Car, Veza and Mikac (2004) and Essink, Nassehi, and Newman (2014) have an almost identical approach to problem modeling, with the only difference being in the structure of the GA (genetic operators, representation of genes and chromosomes, etc.). Oysu and Bingul (2009) presented an approach for milling tool path generation based on optimization of sequences of predetermined contours. This approach gives good results if there is a clear logic for the previous selection of contours,

From the previous brief literature review, it can be concluded that the presented models of automatic tool path generation and optimization are based to a lesser extent on a purely geometric approach or to a greater extent on model discretization and the application of metaheuristic methods for solving the problem of tool path generation and optimization. The lacks of the presented models are almost identical - they are applicable mainly to rough milling processes, they depend on the shape of the contour being processed and on the degree of discretization of the surface.

The goal of the research presented in this paper is to define and demonstrate through experimental results the concept of automatic generation and optimization of the tool path in contour 3-axis milling which is independent of the shape of the contour and

applicable for both rough and finish milling as a starting point for fully autonomous NC code generation.

## 2. The problem definition and formulation

The basis for the automatic generation and optimization of the tool path is the technical documentation (technical drawing, 3D model of the part being processed, etc.) and also the initial shape of the raw material from which the part is made. The information contained in the technical documentation must be recognized in a form suitable for tool path generation. Figure 1 show a typical industrially inspired part in 3D model representation.

**Figure 1.** 3D model of work piece

Figure 2 shows a plane view of the same part, where the hatched surface represents the material that must be removed in order to obtain the shape marked in red, i.e. the final contour of the part. The shape and dimensions of the initial workpiece (marked blu in Figure 1) is predetermined and as such, represents one of the input data in the model.

In order to determine the path of the tool, it is necessary to find a measure of the discretization of the surface being processed (Barclay, Dhokia, and Nassehi 2015) i.e. to determine the size of the set of points and the position of the points that represent the positioning of the center of the tool, having in mind that the tool must be positioned at each point of that set, but also that its movement leads to processing the contour to the final size, that is, to enable the final processing. In order for the tool path to be generated, it is necessary first to determine the tool used to perform the processing and to determine the milling parameters-speeds, feeds and cutting depth. The process of automatic tool path

**Figure 2.** Planar representation of the work piece contour

generation in contour milling can be divided in three steps:

- determination of tools and milling parameters (speed's and feed's)
- discretization of the surface being processed
- tool path generation

## 2.1. Tools and milling parameters

The task of optimizing the contour milling machining is defined at the following way: select the milling parameters speed and feed that meet the quality limits surfaces and optimization criteria (Tanović, Petrakov 2007). The traditional methods for milling parameters calculation are widely known and are well described in the literature. Although the mentioned methods are applicable in everyday practice, nowadays, especially in the conditions of individual and small-batch production, data from the tool manufacturer's catalogue are most often used to determine the tool and milling parameters for the selected cutter. These catalogues are available in electronic form, so determining the tool and parameters using this data is very (ae) easy and fast. Based on the geometry of the surface and the required quality of processing, a tool of the appropriate diameter is chosen in such a way that all segments of the contour can be processed with that tool, but very often, due to the shape of the contour segments, several different tools must be selected. For the purposes research presented in this paper, it is considered that the milling process of the work piece is performed with one tool, because the principle of path generation for each subsequent tool is the same. The manufacturer of the tool according to the type of engagement (Figure 3) and according to the recommended values of the axial ( $a_p$ ) and radial ( $a_e$ ) depth of cut gives the recommended values of the milling parameters.

The radial ( $a_e$ ) and axial depth of cut ( $a_p$ ) are always given as a function of the diameter and material of the tool, the cutting speed  $V_c$  (m/min) is given depending on the material of the work piece, and the step per tooth  $f_z$  (mm/tooth) is given depending on the diameter of the tool, the type of engagement and radial and axial cutting depths. For the purpose of this paper, the speeds and feeds

will be considered as a constant value, while the radial cutting depth can exceed the value determined by the catalogue data, which depends on the contact surface of the tool and the work piece, which will be discussed later. The axial cutting depth is also constant value, but it depends on the depth of the contour, i.e. the height of the work piece, and in case the length of the cutting part of the tool corresponding to the selected sizes is smaller than the height of the work piece, the processing is performed in several passes according to the height of the work piece. Therefore, the number of revolutions of the main spindle, the speed of the auxiliary movement and the axial depth of cut are considered as constant value and with radial depth of cut along with diameter of the tool represent set of input data for the model presented in this paper.

Figure 3. Tool engagement

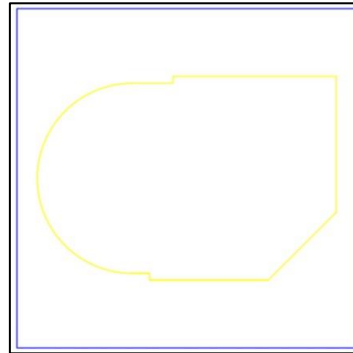

## 2.2 A bitmap based discretization model of the machined surface

In contour milling, the tool path represents an ordered set of points where the tool is positioned, moving in the direction of the auxiliary motion velocity vector. If  $n$  is the number of points in that set, then theoretically there are  $n!$  potential toolpaths. If restrictions are taken into account, then that number decreases but is still very large. Discretization can be modelled as pixelization-mapping of the surface being

processed with a large number of squares (Kumar and Khatak, 2018) basically cover the surface being processed very well, but then their number, that is, the resolution of the grid of squares goes up to 0.01 mm is the usual resolution of today's CNC machines. Such a data set is very large for processing by metaheuristic methods, especially GA, which can lead to the fact that it is not possible to find a solution that converges to the optimal one in an acceptable time (Barclay, Dhokia and Nassehi, 2015). Other approach is surface discretization by placing up an equidistant grid of points on the surface to be processed, but this method gives good results only in cases of rough contour milling (Nassehi, Essink, and Barclay, 2015).

However, if the surface to be processed is represented as a coloured bitmap image, these drawbacks can be avoided. Figure 4 shows initial bitmap image of working piece where the initial work piece contour is coloured blue and the finished part is coloured yellow. In order to discretize a milling, feature the following algorithm must be carried out on initial bitmap image.

- 1) Offset all contours by tool radius to determine the boundaries of the tool positions (Figure 5)
- 2) The contour of the finished part from the previous step offset by the value of allowance for fine milling (Figure 6)
- 3) Colour the finished part and all additional resources in yellow, the allowance for fine processing in red and the rest of the space inside the initial work piece contour in blue (Figure 7)
- 4) Pseudo code of point map algorithm for discretization of machined surface is shown below:  
 for  $i=1$ , bitmapwidth step  $a_e$   
 for  $j=1$ , bitmapheight step  $a_e$   
 if  $\text{PixelColor}(i,j)=\text{blue}$  then  $P(i,j) \in M$   
 next  $j$ , next  $i$

**Figure 4.** Initial stage of discretization

**Figure 5.** Offsetting feature boundary

**Figure 6.** Offsetting for the fine milling

The colour of each pixel that is at a distance equal to the radial depth of cut  $a_e$  from neighbouring pixels is checked, and if it is coloured blue then it belongs to the set of points  $M$  through which the centre of the tool must pass in order to obtain the

machined surface (Figure 8). In this way, all illegal moves of the tool are eliminated because a collision cannot occur between the tool and the work piece or between the tool and the clamping fixture.

Example:

bitmap width:  $X=2000$  px

bitmap height:  $Y=2000$  px

bitmap resolution:  $R=1000$  DPI (px/inch) i.e.  $39.37$  px/mm

The dimensions of the initial workpiece are:

width:  $2000/39.37=50.8$  mm

height:  $2000/39.37=50.8$  mm

tool diameter:  $d=12$

radial cutting depth:  $a_e=1.2$  mm

resolution of the grid points for rough machining:  $1,2 \times 39,37=42,44$  px/mm.

The grid of points for rough machining is defined as points map  $M=[m_{ij}]$  and for above example has 762 points. For rough machining it is more than enough. For fine machining the same algorithm is processed, but with one difference. Every pixel is a point in point map for fine machining (pixels colored in red in Figure 7), and if the allowance for fine machining is 0,2 mm which is common value taken from everyday practice then the number of points in point map for fine machining is 672 points but with resolution of 0,02 mm/px ( $1/39,37$  px/mm) which is enough for fine machining.

Figure 7. Step 3 of point map algorithm

Figure 8. Imposed map of points

The necessary bitmap image (Figure 7) for executing the point map algorithm is very easy to obtain from any CAD software. Radial depth of cut  $a_e$  or *stepover* is the percentage of the tool diameter engaged in material (Figure 9).

Figure 9. Radial depth of cut and TEA

The stepover determines the material removal rate (MRR) and reflects the cutting forces, but only for straight line motions. A parameter which better reflects the cutting force, regardless of the toolpath shape, is the *tool engagement angle-TEA* (Dimitrache, Borangiu and Dogar, 2010) as the amount of sweep subtended by each cutting edge as it engages and leaves the stock. For straight line motions, there is a direct, nonlinear relationship between tool engagement angle and stepover (Tanović and Petrakov, 2007). The engagement angle reaches its maximum ( $360^\circ$ ) when plunging the tool vertically into the material. The next maximum value,

180°, is encountered during a slotting operation; this condition may lead to high thermal stress on the tool, since the chips cannot be evacuated properly. Tool engagement is also known to increase at internal corners in toolpath. The engagement angle also has direct influence on the chip shape, therefore keeping TEA constant ensures consistent chip size and shape throughout the milling process (Dimitrache, Borangiu and Dogar, 2010). A large value of the TEA would result in a large amount of material removed, which certainly increases productivity, but then the cutting resistance is high and the wear of the tool is intense. As there are advantages and disadvantages of a larger or smaller milling angle, in the model considered in this paper, the milling angle  $\theta_{max}$  represents the input value in terms of the target value. Therefore, it is necessary to know TEA at every moment, that is, at every point of the tool path, and by comparing that value with the target, make a decision whether that segment is acceptable or not. In their research Wang, Jang and Stori (2005) presented in detail the process of calculation TEA by determining the overlap of the pixels of the section of the circumference of the tool and the current geometry of the work piece. This way, which is common in literature, involves the discretization of the tool and surface being processed into bit matrices of 0 and 1 and is highly dependent on resolution, which can be very time-consuming and even lead to the impossibility of real-time execution. In the next paragraph, a very simple method for calculating TEA will be presented, which is based on the simulation of the movement of the tool and bitmap representation of work piece.

### 2.3 Simulation algorithm for tool engagement angle calculation

By moving the center of the tool through the points of the points map  $M = [m_{ij}]$ , the chip is removed. As shown in Figure 10, the

contact between the tool and the surface being processed is determined by the length of the circular arc between the first and last point of contact.

Figure 10. Calculation of TEA

Every point T on tool boundary can be represent by  $x = r \cdot \cos\varphi$  and  $y = r \cdot \sin\varphi$ . If  $r=r+1$  then all points outside the tool boundary will be checked but not on tool boundary, which is important because we need to number all blue pixels immediately behind the tool boundary, because the pixels are blue only in the points where the tool has not yet been. The pseudo code is shown below:

```

for every [mij] do
n=1
r=r+1
while φ ≤ 360° do
x = r · cosφ; y = r · sinφ
if PixelColor(x,y)=blue then n=n+1
φ = φ + 0,1
end
end
θM = n/0,02  $\frac{mm}{px}$ 
If θM ≤ θ point C is acceptable
else point C is illegal;

```

By simulating the movement of the tool as shown, it is very easy to calculate the TEA, and what is even more important, the

condition of the work piece is known in any moment i.e. where the tool has passed (white colour) and where it has not (blue colour).

### 2.4 Mathematical formulation of the proposed model

A 3 axes CNC machine moves in both  $x$  and  $y$  directions simultaneously and Euclidean distance function is to be used to calculate the distance between points. In this way a distance matrix matrix  $D=[d_{ij}]$  is created.

Let  $i$  and  $j$  be two arbitrary points from set  $M$ .

#### Input variables

- geometry described by a bitmap image
- the set of points described by the point map  $M=[m_{ij}]$ ,
- the distance matrix  $D=[d_{ij}]$  between the points of the set  $M$
- radial cutting depth  $a_e$  in mm
- maximum TEA  $\theta_{max}$  in degrees
- tool diameter  $d$  in mm
- speed of main spindle  $S$ (mm/rev)

$$\forall j \in \{0 \dots n\} \sum_{i=0}^n Z_{ij} \cdot \psi_{ij} = 0$$

- feed rate  $F_{th}$  (mm/min)
- rapid feed rate  $F_{bh}$  (mm/min)

#### Control variables of the mathematical model

$$X_{ij} = \begin{cases} 1 & \text{if point } i \text{ is immediately by } j \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

$$Y_{ijk} = \begin{cases} 1 & \text{if tool travels from } i \text{ to } k \text{ in same dir.} \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

$$Z_{ij} = \begin{cases} 1 & \text{if } j \text{ is machined} \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

$$\Theta_{ij} \text{ TEA when moving from } i \text{ to } j \quad (4)$$

#### Constraints of mathematical model

1) Constraint that ensure that every point from set  $M$  is visited by the tool at least once

$$\forall j \in \{0 \dots N\} \sum_{i=0}^N X_{ij} > 0 \quad (5)$$

2) Constraint that ensure that tool leaves each point after visting for another

$$\forall j \in \{0 \dots n\} \sum_{i=0}^n X_{ij} = \sum_{k=0}^n X_{jk} \quad (6)$$

3) Constraint that ensure that every point is followed by a different point and path moves on

$$\forall j \in \{0 \dots n\} X_{ii} = 0 \quad (7)$$

4) From each subset of points the tool must be positioned at least once in another point that is not part of the of that subset of points  $\forall Q \subset \{0 \dots n\}: Q \neq \emptyset$

$$\sum_{\{i, j \in N\}: i \in Q, j \in N \setminus Q} X_{ij} + \sum_{\{i, j \in N\}: i \in Q, j \in N \setminus Q} X_{ji} \geq 2 \quad (8)$$

5) Constraint to ensure that the tool engagement angle  $\Theta_{ij}$  must be smaller or equal than the maximum allowed engagement angle  $\Theta_{max}$

$$\forall j \in \{0 \dots n\} \sum_{i=0}^n X_{ij} \cdot \theta_{ij} \leq \theta_{max} \quad (9)$$

6) Constraint that ensure that during the chip removal process, the movement of the tool is allowed only towards neighbour points.

$$\forall j \in \{0 \dots n\} \sum_{i=0}^n Z_{ij} \cdot \psi_{ij} = 0 \quad (9)$$

### The objective function

The objective function of the mathematical model represents the criteria of optimisation. In the observed model the goal is to achieve high productivity, thus minimization of processing time, with minimization of the jerk effect with as uniform tool angle of engagement as possible.

Minimization of the processing time, can be written as:

$$F_{c1} = \min \sum_{i=1}^n \sum_{j=1}^n \left( \frac{d_{ij}}{F_{rh}} + \frac{r_{ij}}{F_{bh}} \right) \cdot X_{ij} \quad (10)$$

where  $d_{ij}$  are the distance between the points of the path in which the tool moves in a feed rate and  $r_{ij}$  the distance between the points of the path in which the tool moves in a rapid rate.

The minimization of the number of changes in the direction of movement of tool, taking into account the control variable defined by expression (2) can be written as:

$$F_{c2} = \min \sum_{i=1}^{n-2} \sum_{j=2}^{n-1} \sum_{k=3}^n \frac{1}{Y_{ijk}} \quad (11)$$

The third goal of optimization is the smallest possible deviation of the TEA from the target value and can be defined as:

$$F_{c3} = \min \sum_{i=1}^n \sum_{j=1}^n |\theta_{ij} - \theta_c| \cdot X_{ij} \quad (12)$$

that is, as a minimization of the deviation of the TEA value at each point of the path in relation to the target value.

The problem of milling path optimization is clearly multi objective optimization problem. For the purpose of this research the method of weight coefficients will be applied.

Determining the weight coefficients can be a problem (Singiresu S.R., 2009) because the vector of weight coefficients controls the optimal solution. Mathematically, the optimal solution obtained with equal weighting coefficients should lead to the smallest conflict between the optimization goals, but in practice it is often not a satisfactory solution, so when determining the weighting coefficients, it is always necessary to have information in the order of priority of the goals. For the purposes of this paper, the greatest weight will be given to achieving maximum productivity so objective function is defined by following expression

$$F_c = 0,5 \cdot F_{c1} + 0,25 \cdot F_{c2} + 0,25 \cdot F_{c3} \quad (13)$$

### **3. Proposed algorithm fo milling path generation and optimization**

An acceptable milling tool path represents permutations of points while respecting the constraints defined in the mathematical model which is basically an integer programming model. Genetic algorithms, as one of the modern, metaheuristic methods, are very suitable for solving this type of problem because in most cases they can find the global optimum with a very high probability (Singiresu S.R., 2009). It should be noted that the efficiency of the genetic algorithm depends on the applied genetic crossover and mutation operators (Umbarkar & Sheth, 2015). There are many literature sources related to this method, i.e. the GA's mechanism is widely known. Furthermore, only short definitions of GA-related terms and explaining the definitions in the observed model's context are given.

#### **3.1. Definition of GA related terms in the context of observed model**

**A gene** in the observed model is the primary

carrier of informations. The point is denoted as  $M$  and every point that should be visited by the tool at least once contain the following informations:

- position defined by coordinates
- condition (machined or no)
- speed at which the tool moves towards the point ( $F_{rh}$  or  $F_{bh}$ )
- ordinal number of point in the path

**An individual or chromosome** is represented by a combinations of genes and it is acceptable solution. In the observed model. this will be acettable tool path.

**The population** is a set of individuals, and in the observed model, it will be a set of all acceptable tool paths.

**The parents** are two acettable tool paths that combine to create new tool path.

**Fitness** is a function that tells us how good each tool path is. In the observed model, the path length is the fitness and it is defined by expression (13) in the mathematical model.

**Crossover** is the genetic operator defined as combining two individuals, i.e. tool paths to create new tool path.

**The mutation** is the genetic operator defined as the process in which one individual or one tool path participates, and the goal is to generate a new tool path. A mutation changes the value of one or more genes on a chromosome. The process of implementation of genetic operator's crossover and mutation in the observed model will be explained later.

### 3.2. Chromosome representation and decoding

In the construction of a genetic algorithm, the first step is to define an appropriate genetic representation or an appropriate coding method. An acceptable representation is the most critical factor influencing all other phases of the GA (Singiresu S.R., 2009). It primarily depends on the model

being observed so that the chromosome coding solution with a vector of real components will be given.

As mentioned earlier in this paper the geometry of working piece is already recognized. The coordinates of every point is known so the distance matrix  $D=[d_{ij}]$  can be easily determined. In the observed model, the tool can pass through any point of the map of points several times, with the fact that it only passes once to remove chips, and it can pass through the same point again only for the purpose of approaching the cutting zone. Thus, the gene in the chromosome is marked with a natural number and represents the ordinal number of the point of the point map through which the tool passes. The tool can move from one point to another either at feed rate or rapid rate depending on whether the chip is removing or tool positioning is performed. Therefore, it is necessary to know the speed with which the tool moves from the point  $i$  and arrives at the point  $j$ . The next segment that describes the trajectory of the cutter is the engagement angle  $\theta_{ij}$  which can be  $\theta_{ij} = 0$  if the tool is moving at rapid rate or  $\theta_{ij} > 0$  if the tool is moving at feed rate. In addition to knowing the x and y coordinates of each path point, it is also necessary to know the z coordinate, i.e. the plane in which the center of the tool moves and the condition of the point i.e. if is previously machined o no. An example of fully decoded chromosome is given in Table 1.

The decoded chromosome enables the creation of a CL (Cutter Load) file, that is, a file that represents the basis for generating NC programs and is generated by all today's CAM systems. For example, 3-5 record in the previous table shows that the tool moved from point 3(22, 6, 50) to point 5 (26, 6, 0) at rapid rate without removing chips by positioning in the plane  $z=50$  (26, 6, 50) and rapid move to  $z=50$  (26, 6, 0). In this way, the entire path of the cutter from point

1 to point 6 can be read, with the order of movement of the tool being 1-3-8-5-4-2-10-7-9-8-3-5-6.

**Table 1.** Decoded chromosome

	1	3	8	5	4	2	10	7	9	8	3	5	6
F (mm/min)	$F_{bh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{rh}$	$F_{bh}$	$F_{bh}$	$F_{rh}$	$F_{rh}$
$\theta_{ij}$ (°)	0	40	42	25	30	35	39	41	42	0	0	0	30
x (mm)	20	22	24	26	28	30	32	32	34	24	22	26	26
y (mm)	6	6	6	6	6	6	6	6	6	6	6	6	10
z (mm)	50	0	0	0	0	0	0	0	0	50	50	0	0
Machined	true	false	false	false	false	false	false	false	false	true	true	false	false

### 3.3. Initial population

Using the distance matrix  $D=[d_{ij}]$ , it is necessary to form another set of points which is very important for generating the initial population. That set K is the set of the closest points of each point of the point map, which contains all the k closest points to the point where the center of the tool is located. In the observed model, there can be up to 24 closest points to each point of the point map, and the x and y coordinates of the members of that set tell to which point the tool can move from any current point of the path. By forming the set K, a part of unacceptable or illegal paths is eliminated, i.e. the constraint defined by expression (9) is implemented. When all points of set K is visited by the tool then next random point of tool path is chosen. At the initial moment, only the points located in the first and last row and the first and last column of the map of points have the condition  $machined=true$  and that point are peripheral points status of peripheral points, all other points have the status  $machined=false$ , i.e. the status of unprocessed points. It is clear that the first point of any milling path must be one of the points with status  $machined=true$ . Furthermore, the algorithm for forming the

initial population is given below:

**Step 1:** Randomly select the initial point from the set of points M with  $machined=true$

**Step 2:** For a randomly selected point from step 1, load the previously determined set of nearest points K to the randomly selected point.

**Step 3:** Randomly choose one point from the set K in the label j that has the status of an unprocessed point i.e.  $machined=false$

**Step 4:** Calculate the milling angle  $\theta_{ij}$  when moving from i to j.

**Step 5:** If  $\theta_{ij} \leq \theta_{max}$ , point j becomes a tool path point. If  $\theta_{ij} \geq \theta_{max}$  then go to step 10.

**Step 6:** Assign status  $machined=true$  at point j.

**Step 7:** Calculate the vector product of vectors and  $\vec{ix}\vec{j}$  if the vector product is different from zero, increase the control variable  $t=t+1$ , if it is equal to zero, the control variable t keeps its previous value.

**Step 8:** Calculate  $|\theta_{ij} - \theta_c|$ . Control variable  $d=d+|\theta_{ij} - \theta_c|$ .

**Step 9:** Check the statuses of the neighboring points of point j. If the statuses are  $machined=true$ , then point j becomes a

peripheral point, ie. the status of point  $j$  machined=true

**Step 10:** Repeat steps 3-9 for each point from the set  $K$ .

**Step 11:** Repeat steps 1-10 for each point in the set  $M$  until all points from the set  $M$  have status machined=true

**Step 12:** Repeat steps 1-11 for each individual from the initial population

By forming the initial population whose size is the input parameter of the genetic algorithm, the initial set of possible tool paths is formed. By choosing the parents, that is, two tool paths, and applying the genetic operators of crossover and mutation, and calculating goodness for each individual, that is, for each tool path, a path that converges to the optimal path is reached.

### 3.4. Fitness calculation

Fitness is a function that defines how good is the created tool path. This implements the goal function given by expression (13) in the mathematical model. The fitness calculation is done with each tool path in the population. The algorithm for fitness calculation is simple and in fact it is the calculation of the variables ProcessingTime, DirectionChange and Deviation.

The ProcessingTime variable is determined as the time it takes the tool to cover the distance between each two adjacent points from the previously formed tool path, taking into account whether the tool moves between the points at a rapid rate or a feed rate. The ProcessingTime is calculated for each path from the population.

The variable DirectionChange is determined as the number of changes in the control variable  $t$  (defined in step 7 of the algorithm for creating the initial population) in the tool path. The number of changes in the control variable  $t$  is calculated for each tool path in the population.

The Deviation variable is determined as the sum of the differences between the TEA and the target value of the TEA. The sum of the differences is defined by the control variable  $d$  (step 8 of the algorithm for creating the initial population). The deviation variable is calculated for each tool path in the population.

When these variables are determined, the fitness of the tool path, is calculated. The calculation method is given by the following pseudo code:

```
Set the TopPath variable to 0
for I=1 do Population size in steps of 1
Assign the  $i$ th toolpath to the variable C1
C1=Path(I)
Assign the toolpath to the variable C2 with the index TopPath C2=Path(TopPath)
If
0.5*ProcessingTime(C1)+0.25*DirectionChange(C1)+0.25*Deviation(C1)<
((0.5*ProcessingTime(C1)+0.25*DirectionChange(C2))+0.25*Deviation(C2))+0.25*Deviation(C2)
Assign the value of the  $i$ -th index to the variable TopPath, that is, save the value of the best fitness in the variable TopPath.
Go to the next passage
```

### 3.5. The parents

The parents represent two toolpaths that combine to create new toolpaths. The selection of parents or paths is done by comparing their fitness. It is clear that the parent should be the path that has the shortest length (the greatest fitness), and when this is determined by comparing with the fitness of other paths, then the logical variable *parent* is assigned the value of truth, ie that path is chosen in the set of paths for crossover. The comparison is repeated until the number of iterations defined by the size of the set of parents, which represents the input size of the genetic algorithm, is fulfilled.

### 3.6. Crossover operator

The crossover is a process in which two individuals are combined to obtain new individuals, ie the selection process selects parents and the newly created individuals are children. The genetic material of a child is a combination of the genetic material of both parents. With the fact that in the problem of path optimization for milling processing, the same points can be included more than once in the same path, so specific crossover operators are used to implement crossing, so specific crossover operators are used to implement the crossing. The reviews of the most common crossover operators used in GA are given in (Umbarkar, Sheth 2015) and in (Padmavathi, Yadlapalli 2017). The Order-base Crossover (OX) operator, was chosen for the realization of crossover operation in this paper. It constructs an offspring by choosing a substring of one parent and preserving the relative order of the elements of the other parent. For example, the following two parent strings: (1 2 3 4 5 6 7 8) and (2 4 6 8 7 5 3 1), and suppose that a first cut point between the second and the third bit and a second one between the fifth and the sixth bit is selected. Hence, (1 2 - 3 4 5 - 6 7 8) and (2 4 - 6 8 7 - 5 3 1). The offspring are created in the following way. Firstly, the string segments between the cut point are copied into the offspring, which give (\* \* 3 4 5 \* \* \*) and (\* \* 6 8 7 \* \* \*). Next, starting from the second cut point of one parent, the rest of the elements are copied in the order in which they appear in the other parent, also starting from the second cut point and omitting the elements that are already present. When the end of the parent string is reached, we continue from its first position. In those example, this gives the following children: (8 7 - 3 4 5 - 1 2 6) and (4 5 - 6 8 7 - 1 2 3).

### 3.7. Mutation operator

Mutation is a process in which one individual or one tool path participates, and the goal is to generate a new tool path. A mutation changes the value of one or more genes in a chromosome. As the gene in the optimization model is a point with coordinates that describe it, which cannot be discarded, and the chromosome represents the path of the tool, there is a specificity of the mutation process in the observed model. Namely, in the classic TSP model, at the point where the mutation is performed, 0 turns into 1, and vice versa. The goodness value must be calculated for the newly created individuals. Thus, a new population is formed, with the same number of individuals as at the beginning. However, in the model for determining the tool path in the the contour milling, it is not possible to remove the gene, because the gene is a point, and the path must include all points at least once. For this, the mutation is done by the process of inversion, that is, by replacing the places of two points in the path with a correspondingly low probability, which represents the input data of the GA. After changing the points in the path, the acceptability of the newly created path is checked, that is, the angle of engagement is checked. Points are chosen randomly until points satisfying the previous condition are found.

#### Pseudo code of proposed GA

Input parameters for GA shown in this paper are: Set of point M, TEA target value, diameter of the tool, the population size, the number of parents, mutation rate and the number of generations.

#### Start

Enter the input parameters  
Create Points map, Distant matrix and  
Matrix of neighbors K of each point

Create Initial population  
 Calculate the fitness of individuals of the first generation  
 Generation = 1  
 Repeat  
     Selection of parents  
     Children = 0  
     Repeat  
         Pick of two parents for a crossover (Parent1, Parent2)  
         Crossover OX (Parent1, Parent2)  
         Mutation  
         Children = Children + 1  
     Until Children = population size-total number of parents  
     Generation = Generation + 1  
     Calculate the fitness of individuals for the current generation  
 Until generation = total number of generations  
**End.**

#### 4. Presentation of the independent software solution, experimental results and discussion

The application in which the previously presented solution is implemented is written in the object-oriented programming language Delphi. Bitmap representation of the image is created base on industrially inspired part in Autocad. Figure 11. shows the initial form of the application. The application consists of several parts:

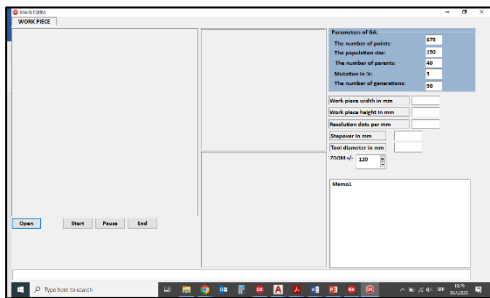

Figure 11. The initial form of the application

In the left is a window where bitmap image is displayed, in upper right corner is the part for entering the genetic algorithm's input parameters, and in the middle there are panels that monitor GA executions, in which the graphic representation of the current tool path is simultaneously displayed. After loading the application, user must choose bitmap by pressing the Open button. By pressing the Start button execution of GA begins with creation of points map, as shown in Figure 12.

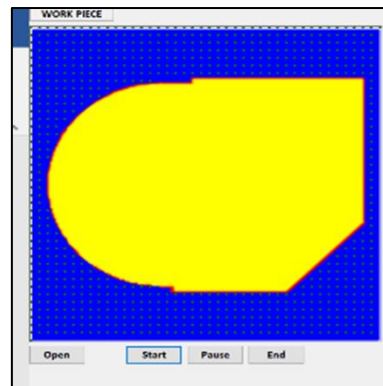

Figure 12. Creation of point map

The middle panel showing current data and graphical display during GA execution and the lower right part of the input screen represents the space in which, during and after the genetic algorithm's execution, the GA execution results are displayed. After the proces of generating and optimizing the tool path) the data necessary for NC code creation are written in a sort of CL (Cutter Load) file prepared for the processing in the appropriate post processors of CNC machines.

##### 4.1. Experimental testing of proposed GA

Unlike many examples that can be found in the literature, where the results of GA execution are shown by varying the degree of mutation, population size, number of

parents, etc., in this research, the proposed GA was previously tested by varying the previously mentioned parameters in order to find the optimal parameters. The tests were done with a constant value of TEA=40 degrees. Then GA was tested by varying TEA and radial depth of cut (stepover) according to Table 2 (Dimitrache, Borangiu and Dogar, 2010).

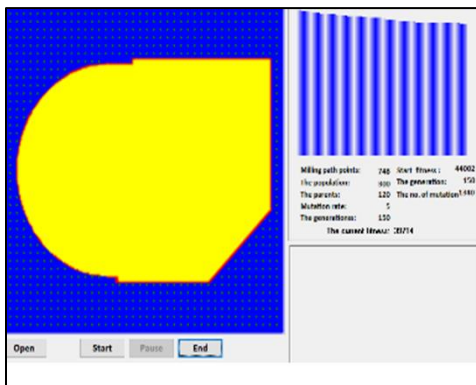

**Table 2.** Relation between  $a_c$  and TEA

$a_c$	10%	25%	50%	75%	85%	95%
TEA	37°	60°	90°	120°	135°	155°

During the extensive testing of GA, it has been shown to give the best results for:

- population size=300
- the number of parents=120
- mutation=5 %
- the number of generations=150

Fitness value was 39714 (Figure 13). With these parameters GA was tested for TEA value given in Table 2.

**Figure 13.** Results of GA testing

The results of GA testing for different TEA values are given in Table 3. It is clear that fitness or the path of the tool that converges to the optimal one, is highly dependent on TEA, because in the formula for calculating the fitness, the highest weight coefficient is given to the objective related to the length of the path.

**Table 3.** Relation between TEA and fitness of the proposed GA

Fitness	39714	20584	16249	11435	10024
TEA	40°	60°	90°	120°	150°

From the results shown in Table 3 it is clear that it is necessary to find the optimal ratio of the diameter of the tool, the tool angle of engagement (TEA) and the radial depth of the cut to have a tool path which converges to optimal one. The results of the previous experiment were needed to carry out the experiment in the real production conditions using the coordinates of the points obtained by executing the proposed GA.

#### 4.2. Experimental testing of proposed GA in real production conditions

The conditions of the experiment are given in Table 4.

**Table 4.** Conditions of the experiment

CNC machine	CNC milling machine IBARMIA ZVX 2000
Control unit	HEIDENHAIN TNC407
The machine working space	2500x500x600 mm
Tool	Carbide millin cutter: HK16822161 Ø16x63x125 mm, 30° TiAlN
Initial work piece dimension	50x50x70 mm
The dimension of finished work piece	40x30x59,9 mm
Materijal	1.4301
Speed of the main spindle	S=1600 o/min
Feed rate	$F_{rh}=100$ mm/min
Rapid rate	$F_{bh}=4000$ mm/min
Radial depth of cut	$a=2$ mm
TEA max value	$\theta_{max}=40^\circ$
The clamping of the piece	Shown on Figure 14
The operation	Contour milling

Figure 14. Clamping of work piece

Figure 15. Finished part

By executing the NC program where the path of the tool was obtained by executing a previously defined algorithm implemented through several programming codes of the Delphi language, the machined contour was obtained, which is shown in Figure 15. It should be noted that the central hole was not the subject of this experiment, but was done due to the test of the drilling tool. By measuring the overall dimensions of the processed piece, it was determined that all dimensions except the width of the piece of 30 mm are within the tolerances of the free measurements, and that the measures of 30 mm deviates by +0.2 from the tolerance of

the free measures, which may be a consequence of inadequately entered correction of the cutter diameter. Figure 16 shows (circled in red) the deviation from the contour defined by the drawing in the transition area (the contour is shown in Figure 13) from a straight line to a curvilinear contour, which is a consequence of the irregular arrangement of points in the map of points in this zone, so that the algorithm for placing the map points should be revised and eventually corrected.

Figure 16. Deviations from measures and shapes

The surface roughness of the machined surface was not measured because it was not part of the experiment. The purpose of the experiment is to determine deviations in the dimensions and shape of the finished piece during processing with the NC program, basically generated by the application of the algorithm described in point 2 of this paper. The total machining time of the piece was 6 min and 15 s. It was concluded that it is necessary to perform another experiment with a corrected algorithm for setting the point map and measuring the surface roughness, comparing the measured values with those required on the drawing of the piece, in order to obtain more complete results of the application of the proposed tool path generation model in contour milling.

## 5. Conclusion

For the classical method of creating NC programs, qualified operators, complex and often expensive software CAM packages are needed, the time of creating the program is relatively long, and there is no guarantee that the time of creating the part will be the least, that is, that the production costs will be reduced to a minimum, because the effectiveness NC programs largely depend on the knowledge or experience of the programmer or operator. One of the alternative approaches, presented in this paper, is the complete autonomy of the NC code generation process during contour milling based on the existing or recognized work piece geometry.

The paper provides a detailed description of the algorithm for mapping the surface to be processed, which, based on experimental results, must undergo minor correction in the part when the length of the contour segment

is less than the recommended radial depth of cut. Also, the cutting zone and the method of calculating the parameters are defined, before all angles of engagement in the cutting zone, and a detailed description of the genetic algorithm used to solve the optimization problem is given. Complete automation of the process is possible as a subject of further research, but it requires very complex computer programming, especially in the part related to the transformation of the coordinates of the optimized path into NC code, taking into account the variety of control units that can be found on modern CNC machines. Also, further research is needed in order to evaluate presented GA with other crossover and mutation operators to improve the speed of execution. The proposed GA was tested only for rough machining and having in mind that the presented algorithm for fine contour milling is the same, the further research will refer to testing and possible corrections for fine contour milling,

## **QUALITY CONTROL IN THE MANUFACTURING INDUSTRY BASED ON THE APPLICATION OF COMPUTER VISION**

***Summary:** Application of technologies based on information communication systems, internet networks, embedded systems, data storage in the cloud, computer vision, machine learning within manufacturing industry leads to a number of advantages in the quality control process. The goal of the work is the development of the system for quality control within production industry with the application of computer vision and algorithms for comparison and analysis. The secondary goal of the work refers to the storage of data on product quality and the control of production machines based on the analyzed data. The result of the application of the mentioned system is reflected in the identification of non-compliant products, which will lead to a reduction of the company's losses.*

***Keywords:** Industry 4.0., Quality 4.0., Cloud, OpenCV, Computer Vision, CNN, SSIM, IOT*

### **1. Introduction**

Product quality control within the manufacturing industry is one of the most important indicators of success companies. The very development of technology and its use within the industry leads to a greater number of detection methods non-conformities and quality control. As the area of the manufacturing industry itself differs from company to company, as well as the non-conformity that can be presented in several ways, several methods of quality control can be applied. One of the ways of quality control is computer vision, which has a huge advantage over manual ways of quality control in terms of the adaptability of the system to a specific purpose, the application of deep learning in the process of making a decision on non-conformity, algorithmic systems (Rožanec et al., 2022, Louw et al. , 2019, Yang et al., 2020).

This technology also has limitations, so it can be used to detect text, color, dimensions, and scratches. The accuracy of the obtained data depends on several factors, the most important of which relates to the algorithm itself used to detect inconsistencies, external factors such as lighting, vibrations, equipment quality, while the speed of the system is directly related to the hardware. The advantage of applying computer vision compared to manual methods of quality control are certainly based on speed, timely information in real time, smaller losses, reduced costs of finishing products or semi-products, reduced production of scrap products, which directly affects company profits (Yang et al., 2020). In addition to the large number of systems based on the application of computer vision for quality control, this area is still under-researched, it is necessary to strive for the development of less complex systems that

will require less software and hardware power and that will achieve results at the same speed. Accordingly, there is a need for the development of this system that will contribute to the efficiency and speed of product non-conformity detection. The main goal of the system developed and presented in this work is the development of a quality control system based on computer vision, where the focus is on external non-conformities of products within the manufacturing industry, where the amount of funds needed for its implementation should be taken into account. The advantages of using this system can be seen in the training of the system where convolutional neural networks were used, the use of which significantly accelerated the training, which makes the system much more adaptable to needs.

In the continuation of the work, a review of the literature will be presented, which will include the current technology that has been applied in the field of product quality with the use of computer vision. Application of Industry 4.0. as well as the very technologies it includes for solving problems in the quality control process.

## 2. Literature review

### 2.1. Quality control in manufacturing industry

Quality control within the framework production industry can be seen as a process that consists of two sub-processes that make up the identification of quality and quality comparison (Powell et al., 2021;). The quality identification process can be seen as the process of determining the current quality of the product by various measurement methods, the comparison process involves comparing the identified quality with the results that need to be achieved (Powell et al., 2021;). Quality of the product is closely related to the user of

the product or service, which is actually a determinant of the level of required and achieved product quality (Rodrigues et al., 2020; Powell et al., 2021;). Seen from the side of the customer or user of the product on alone Product quality is affected by a number of factors of the same and which are often defined standard or user requirements (Carvalho et al., 2021; Rodrigues et al., 2020 ;). Also, the time of use of a product can define the necessary quality when it is used in industry or when it is used for general use. Quality can be expressed in a number of ways, the basic way of expressing quality is numerically, that is, when talking about some numerical values, it can also be expressed in nominal scales, descriptively, yes or no.

### 2.2. Computer vision

Computer vision as the basis of the system presented in this work is based on the acquisition, processing and creation of data. The technological pillar of computer vision is based on the use of a camera that is applied for the data acquisition process (Stavropoulos et al., 2020;), and it can be applied industrial dedicated cameras as well as general purpose cameras. When it comes to data processing itself, it can be performed in several ways, the most common used by industrial computers while they are all more commonly used general purpose computers viewed from the aspect of finance (Stavropoulos et al., 2020;). The basis computer vision consists of algorithms applied for object tracking, dimensional control, object selection, object recognition, etc. (Stavropoulos et al., 2020;). The complexity of the algorithm directly affects the speed of the system, which is of high importance in some application cases. In order to increase the speed, they are often used and neural networks (Almazán-Lázaro et al., 2022;). In order to achieve satisfactory system performance, which is reflected in accuracy, speed, and the necessary financial

resources, it is necessary to strive to reduce complexity of the algorithm and at the same time maintain or increase its accuracy (Almazán-Lázaro et al., 2022;). In order to achieve satisfactory system performance, which is reflected in accuracy, speed, and the necessary financial resources, it is necessary to strive to reduce the complexity of the algorithm and at the same time maintain or increase its accuracy (Almazán-Lázaro et al., 2022;). Also, the very functionality of the computer vision system can be affected by external factors such as lighting, image resolution, vibrations, distance, etc., in order to increase accuracy of these systems, it is necessary to strive to reduce the influence of the mentioned factors. Today, computer vision finds application in many industrial fields, and its contributions in the application of control quality can be observed through the reduction of scrap, reduction of the number of finished products, controlled production, implementation on industrial robots where it increases the precision of the robot's gait as well as the download position, recognition of different situation, product palletization, control of industrial lines, reduction of the required number of employees in quality control positions (Vukicevic et al., 2019).

### 2.3. Industry 4.0.

Application of Industry 4.0. in the quality control process, it enables the implementation of modern technologies that directly affect the quality control process itself (Culot et al., 2020). The main goal of the application of Industry 4.0. is based on easier and faster execution industrial processes, obtaining more accurate data, reducing the possibility of errors, all with a combination of the application of already implemented technology and new ones (Bigliardi et al., 2020; Horváth et al., 2019). One of the indicators of success applications of industry 4.0. is also reflected in process

control, adaptability system, availability (Albers et al., 2016). The application of internet networks, sensor systems that can independently communicate and collect data is called IIOT (Industrial Internet of things), also this technology includes a database as well as control industrial machines (Bal et al., 2019; Muller 2019; Tupa et al., 2017, Singh et al., 2019). Seen from the side of software that is applied within Industry 4.0. and depending on herself there are a number of industrial areas software systems, tools that lead to cost reduction, faster work, increase efficiency and effectiveness as well as loss reduction (Mijailović et al., 2020). From the hardware perspective of Industry 4.0. implies the application of microcontroller platforms, programmable logic controller, which together implemented in the quality control process and within one machine represent embedded systems (Pasika et al., 2020; Izaddoost et al., 2020; Kullig et al., 2020). Big data provides the ability to store large amounts of data that can be analyzed further to help predict future system failure. With the use of industrial cameras, it is possible to obtain quality data, which further, with the use of deep learning, can lead to a reduction in the possibility of errors. (Maurizio et al, 2021).

### 3. Case study

Within this chapter it will be presented a system that was developed for visual quality control in the production industry of small and medium-sized companies with the use of opencv library, computer vision, cloud system, CNN (Convolutional neural network). Since quality control is performed manually in most small and medium-sized companies, the goal of this paper is the development of an adaptable system for application in the field of visual quality control. Current quality control process: an employee from the quality department supervises the production as well as the products themselves, controlling the

essential characteristics of the product for its functionality. Which means that an employee periodically monitors a production machine and the semi-finished products it produces, as he needs a certain amount of time to check all machines. According to the above, if after the departure of the employee who will perform the quality control process on a certain machine, it produces a non-compliant product, it will continue to do so until he reaches the same machine again. The presented problem can be solved with the application of computer vision if it is a surface one non-compliance. The working principle of the presented system is as follows: based on data acquisition, their processing is performed, after which the system's reaction and data storage take place. Acquisition process data processing is done with the help of system hardware using a camera, data processing in the specific case of photos is done with the use of opencv libraries, TensorFlow library, CNN (convolutional neural network) and non-conformity detection algorithms, the system's reaction is the process of stopping further production if the defined number of non-conformities is exceeded products, data storage is done in real time on the cloud system.

### 3.1. System software

The work process of the presented system can be observed in the following way, when starting the system, it is necessary to initially train the system, that is, to define the non-conformity detection classes. The user of the system performs the training by placing images of non-compliant products in the database from where the system will use these images as reference images, that is, images with which it will compare new images downloaded from the production machine. After training, the system can be put into operation, training must be performed every time the product is

changed. Based on training and neural networks as well as a comparison algorithm, the system recognizes non-compliance, prints the result of non-compliance in percentages and stores the data on the cloud. Within the aforementioned system, the SSIM (Structural Similarity Index) algorithm was used, which compares pixel by pixel the reference image and the image currently collected by this system, calculates the squared error that is created and caused by different pixels. On the very result of algorithm and the accuracy of the system can be affected more factor, the position of the camera must always be in the same location in relation to the product, lighting can affect the quality itself photos and thus the result algorithm, if it is necessary to add the source of illumination must be addressed attention to the product itself, must not come to glare or shadows, vibration is essential prevent them from affecting the movement cameras. In Figure 2, you can see an example of an image of a compliant product that was used to test the operation of the algorithm, all tests of the algorithm were performed within the premises university, laboratory center for quality.

**Figure 2.** Example of a compliant product  
Source: Author

It can be seen in Figure 2 example of a compliant product that does not have a non-conformity. After placing one or more reference images, the user of the system, as well as placing the hardware at the physical location where the acquisition will be

performed, can start the system. The system can also be used to check products for non-compliance or if already collected images are used. In Figure 3, you can see the non-conforming semi-product that was used in the comparison process.

As can be seen in Figure 3. the product has damage caused during the production process. When comparing picture 3 with picture 2, the result of the algorithm is 0.9258, i.e 92.5% similarity. Figure 4 shows the result of the algorithm.

**Figure 3.** Non-compliant product  
Source: Author

```
SSIM compare 1 image A new and image B: 0.9258742417832705
SSIM for compare 2 image A new and image A: 1.0
```

**Figure 4.** Comparison result  
Source: Author

As can be seen from the results of the algorithm, the similarity of image 2 and image 3 is 92.5%, i.e. 7.5% are non-compliant pixels in the specific case of non-compliance. After the collected and processed data is stored on the cloud system in thingspeak cloud was used within this system, an example of stored data collected by this system can be seen in Figure 5.

We can additionally process and display data stored in the cloud in several ways, the advantage of cloud data is its availability.

**Figure 5.** Data stored in the cloud

## 4. Discussion

After analyzing the work of the sector for quality in small and medium-sized companies in Serbia, it was concluded that the quality control process is still carried out manually today mainly due to the amount of funds needed to implement modern solutions. When it comes to the funds that will be invested in the system, it is necessary to reduce the error of the system by reducing the price, to adjust system performance available hardware, enable simple user interaction. An advantage this system can be viewed from the aspect of adaptability in terms of changing the image acquisition location itself, even though it is embedded-implemented in an already existing system or machine, it can be moved to another location. On the other hand, the disadvantages of the system are its sensitivity to external factors that directly affect the quality system operation. The implemented system is implemented on one production machine, which means that it is necessary on every machine implement the same system where they would get a wide network of data and control over the entire production of a company, which is actually another goal. By reducing the occurrence of non-compliant products or even their complete elimination, the company's profit is directly affected, as well as the efficiency

and speed of production response to market demand, quality increases production.

## 5. Conclusion

The initial goal of this study which refers to the development of the control system product quality within production industry was successfully implemented, the results of the system are presented. The presented system is a universal solution that can be applied both on the production machines themselves and can be set up within the quality center for quality control of several different products. Depending on the location of the system application, it is necessary to pay attention to the external factors that may affect accuracy the result of the system. Collected and presented data is stored on cloud system in real time, as far as possible allows viewing of data in each moment. If viewed from the aspect networking of the entire production of one companies where on every production if one such system were implemented in each machine, they would have an overview of the current state of production, where they would have a defined number of non-compliant products, good products and products that are going to be finished. Also, by networking the machines, we can obtain data on the total efficiency for each of the machines in production. Quality control

represents one of the most important processes in every production company which is from of essential importance for the development of the company as well as the ultimate profit of the company, hence the goal for the development of the quality control system, the secondary goal starts from the fact that there are currently not enough experts in the field of quality control, also the application of such systems reduces the need for experts and increases the availability data. The limitations of this study are related to external factors that can affect the accuracy of the system, one of the main factors is related to the position of the product that the camera will photograph, the product must always be photographed in the same position so that the data is as accurate as possible. Given that the system is based on the application of the ssim algorithm, which is in conjunction with CNN, and functions in the manner presented in this study, it represents a unique solution based on the goals of this study. Future directions of research will be based on the implementation of several different algorithms in the process of detecting non-compliant products, which will further reduce the possibility of system errors, as well as reducing the influence of external factors on the operation of the system.

## DETECTION AND RECOGNITION OF ROAD SIGNS USING YOLOV5

**Abstract:** *In the field of deep learning, a convolutional neural network is a class of artificial neural networks that became dominant in various computer vision tasks, which is widely used to solve complex problems in various areas, including driver assistance systems in the auto- motive field. Convolutional neural networks overcome the limitations of others conventional machine learning approaches since they are designed to automatically and adaptively learn the spatial characteristics of features in an image. In this paper, we are going to evaluate the inference and accuracy of YOLOv5s, for effective traffic sign detection in various environments.*

**Keywords:** ADAS; CNN; traffic sign detection; YOLO

### 1. Introduction

Road signs are as old as the roads, traffic signs are a crucial part of our road infrastructure, they provide essential information to road users without these useful signs, we would encounter a higher rate of accidents.

In the race to develop autonomous vehicles, without the information of what is around these vehicles and their precise location, such a car cannot operate without risk. It is for this reason that the detection of traffic signs plays an essential role in autonomous vehicle systems, which are required to recognize and understand these traffic signs to ensure they follow road regulations.

In recent years, significant progress has been made in the field of computer vision thanks to the development of deep learning techniques such as convolutional neural networks (CNN) that have emerged from the study of the human and animal brain. In recent years, most of the state- of-the-art object-detection algorithms have used convolutional neural networks (CNNs) and

have achieved fruitful results in target detection tasks, such as EfficientDet [1] and YOLO algorithm.

YOLO [2] is an acronym for the term "You Only Look Once". It is an algorithm that identifies and detects the different objects in a real-time image. This model divides the image into several cells, if the center of an object is in a certain cell, the latter is responsible for detecting that object.

YOLOv5 [3] is the last version of the YOLO family, which is a model that consists of a single CNN which makes it very fast compared to other detection methods like R-CNN and Faster R-CNN [4].

One of the main advantages of YOLOv5 for traffic sign recognition is its speed and efficiency. YOLOv5 is based on a "darknet" architecture that is designed to be fast and efficient, making it ideal for real-time applications such as traffic sign recognition. This allows YOLOv5 to process images and videos quickly, even on low-power devices, making it a good choice for use in autonomous vehicles and other on-the-go applications. This paper contains:

### 2.1. Single-stage and two-stage algorithms

Modern object detection models can be divided into two categories: two-stage detectors and single-stage detectors. Two-step detection models like R-CNN use two networks to carry out the task of proposing the regions and the task of classification, while one-stage models perform both of these tasks by a single network. The proposal of the regions is carried out by what is called RPN (Region Proposal Network).

RPN is used to find areas where search for the objects in order to reduce the computation time, this is done by generating bounding box proposals each with the probability that an object exists in this region. After generating a list of locations possible objects, a convolutional feature extraction is performed on each candidate region. In the second step, the content of each framing box is classified, to decide which ones to keep and which to eliminate. In general, two-stage architectures achieve better accuracy, but they are slower than one-stage architectures. The biggest drawback of two-stage architectures is that they do not excel at performing real-time detection and require multiple GPUs to train the model[5], thus, the YOLO model has been proposed to address these limitations.

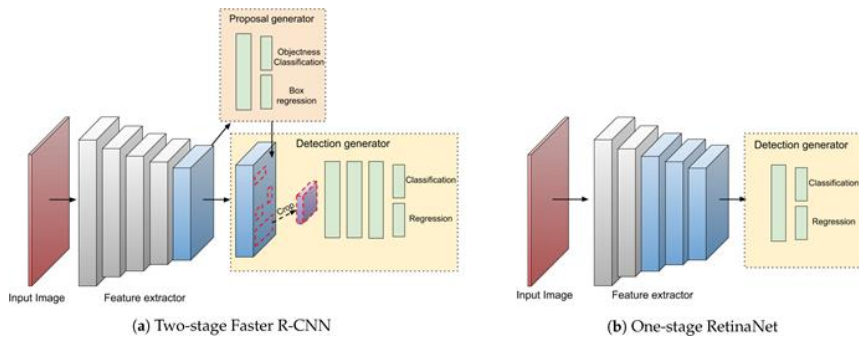

Figure 1. Example of single-stage algorithm and a two-stage algorithm

### 2.2. Introduction of YOLO

YOLO is an acronym for the term "You Only Look Once". This is an algorithm that identifies and detects the different objects in a real-time picture. This model divides the image into several cells, if the center of an object is in a certain cell, the latter is responsible for the detection of this object and it consists of a single CNN which makes it very fast compared to other detection methods like R-CNN and Faster R-CNN. In all object detection architectures, the first step is in extracting features from the input

image through a convolutional network, the depth and type of convolutional backbone used in these architectures affects the speed, accuracy, and memory usage of the model. Recent object detection models have a "Backbone" which is a convolutional neural network used to extract feature keys of an input image, the depth and the type of the convolutional "Backbone" used in the model affect the speed, accuracy, and memory usage of the model. The second component is the "Neck" which creates feature pyramids, these pyramids help models successfully generalize objects. It helps in

the identification of the same object in different scales and sizes, and performs an aggregation on the characteristics and transmits it to the third component called "Head". The "Head" part of the model is mainly used for the last stage of detection. It applies the bounding boxes to the objects and calculates final output vectors with predictions of the classes. YOLO's model can be applied in many fields which depends on fast object detection, and although the prediction speed of the model was very high, the performance was still not comparable to Faster-RCNN when it was introduced for the first time.

YOLOv2 and YOLO 9000 have been released in 2016, YOLOv2 achieved a mAP of 76.8% mAP at 67 FPS and 78.6% at 67 FPS. YOLO 9000 [6] uses the architecture of YOLO v2 but it is able to detect more than 9000 classes. However, the mAP value of YOLO 9000 is only 19.7%. The previous YOLO architecture had many problems. She made a lot of location errors and had a bad "recall". So, the objective of the new article was to improve these defects of YOLO, while maintaining the speed of architecture. YOLOv2 uses a convolutional neural network called DarkNet as feature extractor. As a result of these improvements, YOLOv2 offers a good accuracy and detection speed. At 67 FPS, YOLOv2 can give a 76.8% mAP, at 40 FPS the detector gives an accuracy of 78.6% mAP, a better accuracy than other state-of-the-art models such as Faster RCNN and SSD while running much faster than these models. The 3rd version of YOLO, called YOLOv3 was released in 2018 by the same authors of YOLO and YOLOv2. There are major differences between The architecture of YOLOv2 YOLOv3 and older versions in terms of speed and accuracy. YOLOv2 and YOLOv3 are worlds apart in terms of accuracy, speed, and architecture. YOLOv2 uses Darknet-19 as a feature extractor base, while YOLOv3 now uses Darknet-53. Darknet-53 is a

"Backbone" directed by YOLO creators Joseph Redmon and Ali Farhadi. According to their articles, Darknet-53 is 1.5 times faster than ResNet101. This accuracy means no compromise between accuracy and speed for Darknet backbones, because Darknet-53 is still as accurate as ResNet-152 but twice as fast. In addition, you can easily switch between speed and precision by simply changing the size of the model, without the need for re-train the whole model. YOLOv3 also increased mAP for small objects by 13.3%, which is a huge improvement over YOLOv2.

### 2.3. YOLOv5

YOLOv5 uses CSPNet (Cross Stage Partial Network) as a Backbone, which showed significant improvements in the time of processing using deeper networks. The problem with previous networks is that they required very heavy inference calculations. Cross Stage Partial Network (CSPNet) was created with the aim of solving this problem, by allowing networks more flexibility by including feature maps at the beginning and end of each network step. This avoids having duplicate gradients in the network, because the information is similar between the beginning and the end of each step.

In YOLOv5, PANet (Path Aggregation Network) plays the role of the Neck of the model, it consists of a series of layers to combine and aggregate the image features to pass them to the prediction layers.

The Head of YOLOv5 remains the same as the YOLOv3 [7] and YOLOv4 [8] versions. YOLOv5 has several varieties of pre-trained models. The difference between them is a trade-off between model size and inference time, The YOLOv5s version is small in size but not the most accurate, while the YOLOv5x version is the biggest in size but it is the best of the YOLOv5 family in terms of accuracy.

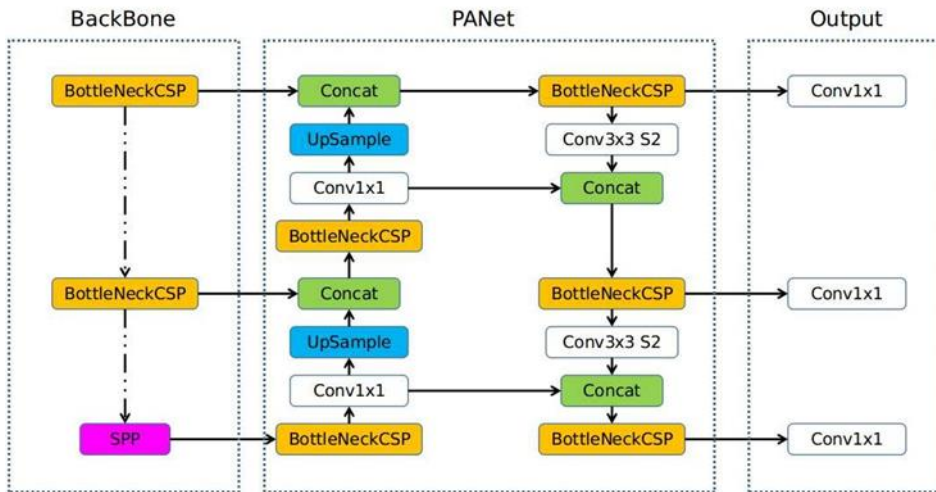

**2.4. Related work**

Current research in the field of computer vision involves building a better image detection system for comprehensive machine learning use. Each new decade have seen the introduction of new traffic signs. The first stage observes traffic signs determining the proper placement of traffic signs in relation to the size and location of each sign. The second stage of the project is the process of displaying an image and understanding the different signs based on colors and shapes associated with them. Traffic sign detection is commonly used in ADAS. Neural Network Classifiers like CNN use classifiers to categorize data in general, issues with object recognition persist in certain models with unfair highlights. Using the word CNN is more appropriate when referring to the subject.

In the last years, many researchers have worked on the detection and recognition of traffic signs using different object detection models.

Mulyanto, A. [9] used YOLOv4 to perform the detection on a dataset of traffic signs from Indonesia, since the research that was done the model showed a main average accuracy of (mAP@0.5) of 74.91% for 26 classes of traffic signs. However, the weak point of their model was the recognition of images of panels that are strongly identical, small differences between some Panel categories seem to pose challenges for deep learning and show the limitations of YOLOv4. Despite this, the model satisfies the requirements of ADAS (Advanced driver assistance system) to provide reliable information to drivers related to the presence of traffic signs on the road.

Overview of YOLOv5

**Figure 2.** Architecture of YOLOv5

C. Dewi [10] proposes a study which analyzes and compares CNN models and extractors features, in particular the two object detection models; YOLOv3 and YOLOv4. This comparison, uses images that

contains 60 traffic signs in different conditions and environments. Their work also presents an approach that combines synthetic images with real images in order to improve the diversity of datasets

and check the effectiveness of dataset synthetics. They concluded that YOLOv4 is more accurate than YOLOv3 using a dataset that combines original images with synthetic images, obtaining an accuracy of 84.9% for YOLOv3 and 89.33% for YOLOv4. This study also shows that training a model with a combination original images and generated images, improves performance when compared to the mere use of the original images.

Zhang et al.[11] modified the number of convolutional layers in the network based on YOLOv2, proposed an improved single-stage traffic sign detector and using Chinese Traffic Sign Dataset Training in an effort to make it more adapted to Chinese Street View, a novel Perceptual Generative Adversarial Networks Developed to detect small flow signs, which improves detection performance and generate super-resolution maps for small signs.

### 3. Approach

#### 3.1. Dataset

A dataset is a group of annotated images. Annotation means specifying the position and the class of the object. Each dataset contains a specific number of classes. Mapillary [12] is a crowdsourced and open-source sharing service for images, Mapillary offers different capture modes, including on foot, on a bicycle or on a car. With data from 190 countries, Mapillary Traffic Sign Dataset is one of the largest traffic sign datasets with great variability in conditions, weather, time of the day and camera sensors and viewpoints, which is publicly available for use in machine learning, to detect and recognize traffic signs.

The Mapillary traffic sign dataset of fully annotated images consists of 52,000 images that reach a total size of 41.5 GB, distributed over more than 300 different classes. Because of ram and storage limitations, it

was necessary to choose a few classes among these 300 classes to work on them. The following classes were retained with a total of 5772 instances:

- regulatory-keep-right-g1: 1242 instances.
- regulatory-no-entry-g1: 2048 instances.
- regulatory-yield-g1: 2775 instances.
- warning-pedestrians-crossing-g4: 1124 instances.
- regulatory-stop-g1: 1386 instances.

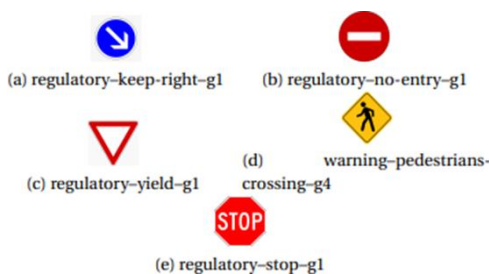

Figure 3. Retained classes for training

#### 3.2. Training the model

The models are trained on 5772 instances from the Mapillary road traffic signs dataset in five classes: keep right, no entry, yield, warning pedestrians crossing and stop. The model is trained for 200 epochs, with batch sizes ranging from 32 up to 80 using Google-Colab's Tesla T4 GPU, and 16GB of VRAM. Google Colab is a hosted service of Jupyter notebook that requires no configuration and allows access without charge to computing resources, including GPUs. Google Colab is a complete tool for training and testing quickly machine learning models without having a hardware limitation.

Before the training process, it is necessary to divide it into three parts: training, testing, and validation.

The training data will be used to train the model during the machine learning process. The validation data will be used to tune the

hyperparameters to achieve the best possible configuration. The model is trained on the training set and simultaneously evaluated on the validation set after each epoch to optimize the model performance.

The test data will be used to verify the performance of the trained model, in order to avoid errors or anomalies, and to achieve performance characteristics such as accuracy and recall.

There are no strict rules on partitioning, but if there are multiple hyperparameters to tune, the machine learning model requires a larger validation set than in less complex cases, typically putting 70% of the data in the training set, 20% in the validation set, and 10% in test set. To start the training, it is necessary to specify the dataset, the batch size (batch-size), image size (image-size), and either weights pre-trained or randomly generated weights. Before changing any parameter, it is recommended to train the model first with the default parameters to establish a performance base on which to improve.

Epoch: At each epoch, an entire data set is transmitted to the neural network once. As the number of epoch increases, the weights of the neural network are modified more times and the model goes from underfitting to an equilibrium point and then to overtraining.

Ultralytics suggests starting with 200 epochs. If this produces a overfitting we reduce the epochs. If overfitting does not occur after 200 epochs, one trains the model longer, i.e. 300, 600, 1200 epochs, etc.

Batch-size: Since an epoch is too large to transmit it to the neural network at a time, it must be divided into several batches (batch) smaller. The batch size or batch-size is the number of samples (in our case, the pictures) in each batch. In the case of YOLOv5, it is better to use the largest batchsize allowed by our hardware, since a small value of batch-size produces poor batch standard statistics and should be avoided.

Image size: The larger the image size, the results are generally better, but the model takes longer to train, the default image size value for YOLOv5s is 640, in most cases of good results can be obtained without modification on the default value of image-size, so the value 640 is retained for our training.

The training batch size has a big impact on GPU memory required for training a neural network, the larger the batch size, the more images are transmitted through the neural network at once, this will directly cause the required GPU memory to increase. We start with a large batch size value of 128, this causes the training process to stop prematurely since the required GPU memory is greater than the one available, we reduce the lot size value and we run the training again and repeat this process until we find the highest value possible with our GPU memory for the batch size, the value we end up with for the batch-size after this process is 80.

## 4. Numeric evaluation

### 4.1. Evaluation metrics

Precision, which measures the accuracy of our predictions. that is, the percentage of predictions that are correct.

$$Precision = \frac{TP}{TP + FP}$$

Recall is the percentage of true positives, among the total number of real objects. For example, if a model correctly detects 90 people in an image or there are 100 people, the recall is 90%.

$$Recall = \frac{TP}{TP + FN}$$

- TP (True Positive) : the case where the prediction is positive, and the

actual value is actually positive. Example: The model detects the presence of a traffic sign, and the sign actually exists in the image.

- FP (False Positive) : cases where the prediction is positive, but the actual value is negative. Example: The model detects the presence of a traffic sign, but the sign does not actually exist in the image.
- TN (True Negative) : cases where the prediction is negative, and the actual value is actually negative. Example: The model does not detect any traffic signs, and indeed no signs exist in the image.
- FN (False Negative) : cases where the prediction is negative, but the actual value is positive. Example: The model does not detect any traffic signs, but the image does indeed contain a sign.

The mAP value (mean average precision) is a popular evaluation metric used for object detection, many object detection algorithms, such as SSD, Faster R-CNN and YOLO, use the mAP value to evaluate their models for research publication.

To calculate the mAP value, we use the intersection on union for that we need:

- The actual bounding boxes, i.e. the bounding boxes that specify where our object is in the image labeled by hand in the test set.
- The bounding boxes predicted by our model.

The calculation of the intersection on the union can be determined via the following formula:

$$IoU = \text{Areaofoverlap} / \text{Areaofunion}$$

## 4.2. Results

Once a model has been trained, it is necessary to be able to evaluate its

performance. The model changes its weights through the training set, it does this by reducing the result of the cost function for the training set.

An good way to verify the effectiveness of the model is to observe the curve of the loss function during training, if the predictions deviate too much from the actual results, the loss function would take a very large number.

The loss function is a method for evaluating how much an algorithm models the training data, using an optimization function, the loss function learns to reduce the prediction error over time.

Figure 4. Loss curves for 200 epochs

According to the evolution curve of the loss function that we obtained, the model converges, we also observe a slight overfitting, because the cost function on the training set is smaller than on the validation set, so it is not possible to continue training to improve performance after that point; the most optimal results observed were during the 76th epoch.

Figure 5. Correctly classified image

There are three parameters used to evaluate the YOLOv5 model from the training results, namely the Precision, Recall and mean Average Precision (mAP).

	mAP@.5	P	R
All	63.8%	77.6%	58.6%
regulatory-keep-right-g1	68.1%	78.2%	58.3%
regulatory-no-entry-g1	52.9%	63.2%	51.5%
regulatory-yield-g1	69.8%	85.5%	65.8%
warning-pedestrians-crossing-g4	60.7%	72.7%	57.9%
regulatory-stop-g1	67.6%	88.3%	59.4%

**Figure 6.** Results table for a batch-size of 80

According to Fig. 5., the experimental result shows that the system returns 78.2%, 63.2%, 85.5%, 72.7%, 88.3% precision rate for 1st, 2nd, 3rd, 4th, and 5th sign, respectively, this gives us a mean precision of 77.6%. This table describes the performance of the proposed approach on Mapillary

	mAP@.5	P	R
All	63.7%	80.5%	54.1%
regulatory-keep-right-g1	68.8%	85.9%	56.3%
regulatory-no-entry-g1	52.9%	73.2%	44%
regulatory-yield-g1	68.1%	92.4%	60%
warning-pedestrians-crossing-g4	61.4%	75.9%	52.5%
regulatory-stop-g1	67.3%	74.9%	57.5%

**Figure 7.** Results table for a batch-size of 64 traffic sign recognition using standard evaluation metrics.

These tables display that the five classes are recognized with a mean Average Precision(mAP) of 63,7%. For the five categories YOLOv5 achieved a precision of above 80% using a batch-size of 64. However when using a batch-size of 80 the precision value is less than 80%, this is because the amount of training data and time to train the model and some images may be identical. This shows that even if the documentation recommends using the highest possible batch-size value for better performance, the model may benefit from using a smaller value such as 64 in our case, however using an even smaller value ie: 32; did not produce better results.

When comparing these results with a paper that implemented YOLOv4- based CSP-

DarkNet53 deep learning model using the Indonesia Traffic Signs (ITS) dataset, that obtained a performance with the main average Precision (mAP@0.5) of 74.91% for six categories but a precision of 74%.

**Figure 8.** Incorrectly classified image

Object detectors such as YOLOv5 are easy to be deceived by objects similar to road signs. One of the main issues is that the ability of the object detector is limited in certain cases, for example a reflection of the traffic sign, or an object that is similar in shape which is just a local pattern of the whole image, but ignores the other information like background.

## 5. Conclusion

One of the main advantages of YOLOv5 is its ability to detect objects in real-time. This is particularly important in the context of traffic sign recognition, where the ability to quickly and accurately identify traffic signs is crucial for ensuring the safety of drivers and pedestrians.

Another strength of YOLOv5 is its ability to accurately detect and classify a wide range of objects, including traffic signs. This is achieved through the use of convolutional neural networks (CNNs), which are able to learn complex patterns in visual data. Another key advantage of YOLOv5 for traffic sign recognition is its ability to handle

a wide range of conditions and scenarios. YOLOv5 is trained on a large dataset of images and videos that includes a wide variety of conditions, including different lighting conditions, weather, and backgrounds. This allows YOLOv5 to generalize well and handle a wide range of scenarios, making it robust and reliable for traffic sign recognition.

In addition, YOLOv5 is able to make high-quality predictions with a high level of accuracy. YOLOv5 uses a single neural network to make predictions, which allows it to make predictions that are more accurate and more consistent than other models that use multiple networks. This makes YOLOv5 a good choice for applications where accuracy is critical, such as traffic sign recognition.

In terms of limitations, one potential issue with using YOLOv5 for traffic sign

recognition is its reliance on large amounts of labeled training data. This can be a challenge in some contexts, where there may be limited availability of annotated traffic sign images.

Additionally, YOLOv5 may not always be able to accurately detect and classify traffic signs in challenging conditions, such as low lighting or the presence of clutter. Further research and development is needed to improve the robustness of YOLOv5 in these scenarios.

Overall, YOLOv5 has great potential for use in traffic sign recognition, due to its ability to detect objects in real-time and its strong performance on a wide range of tasks. However, further research and development is needed to address potential limitations and improve its performance in challenging conditions.

## **IDENTIFICATION OF PRODUCT NON-CONFORMITIES USING COMPUTER VISION ALGORITHMS**

*Summary: The implementation of computer vision in the process of identifying non-conforming products, as well as the application of technologies based on Internet networks, deep learning, large databases within the manufacturing industry leads to the emergence of quality 4.0. Today, the application of computer vision as well as non-conformity detection algorithms in the manufacturing industry can be seen as technological pillars of quality 4.0, which is in direct connection with the company's operations. The main goal of the work is the development of a system for identifying non-compliant products within the manufacturing industry, where the focus is on the application of technologies based on computer vision. The secondary goal of the work refers to the reduction of the necessary funds for the implementation of the system on production machines, the development of a universal, flexible system, where the timely identification of non-compliant products will reduce the company's losses.*

**Keywords:** Industry 4.0., Quality 4.0. Cloud, Computer vision, OpenCV, Hough transform, Real time

### **1. Introduction**

Timely identification of the number of non-compliant products within the production industry, where the focus is on each production machine as well as the product itself, leads to a number of advantages on the way to successful business. Currently, a number of ways to identify non-compliant products can be found on the market. Of course, depending on the production of a specific product, the method of identifying non-conformity, i.e. the application of a certain technology, also depends. Viewed from the aspect of surface non-conformity of the product, identification can be done using technology based on computer vision (Yu et al., 2019). The advantage of applying this technology compared to others is the adaptability of the system, independence,

accuracy, response time considering that they represent real time systems, as well as the price of such systems (Ligarski 2012). The implementation of computer vision in the process of identifying product non-conformities implies the use of algorithms that will analyze and detect images, as well as a number of libraries that are necessary both for calculations and for linking algorithms, the most significant being the use of the OpenCV library (Chai et al., 2021). The basic processes of computer vision are data acquisition and data processing, problems that may occur in the data acquisition process relate to external factors that may affect the quality of the collected data, while problems in data processing may relate to the complexity of the applied algorithms as well as the time that is required for the processing process

---

Corresponding author: Đorđe Mijailović  
[Email: mijailovicdjordje3@gmail.com](mailto:mijailovicdjordje3@gmail.com)

itself. Considering that this technology can be applied for the detection of surface inconsistency, and according to the algorithms used, it can be divided into systems developed for the detection of contours, objects, color, text, dimensions. Certainly, the application of computer vision in the process of identification of non-compliant products brings a number of advantages compared to traditional methods that were based on the training of employees or experts in the field of quality and who performed the identification process visually. The main goal of this study stems from the need to develop a quality control system that will work independently without the assistance of an employee. Although there are a large number of researchers who have done case studies in the field of quality control using computer vision technology, there is still a need for further development of such systems that will focus on contour detection in the shortest possible time interval and with minimal hardware requirements. Secondary objectives relate to the storage of data collected by this case study, data analysis. The advantages of the application of this case study compared to the traditional methods of identification of product non-conformity are reflected in the timely operation of the system, the reduction of the production of non-conforming products, the availability of data, and the reduction of production errors. The contributions of this study derive from the advantages of implementing algorithms that are related to the time required for contour detection in the specific case of circle detection, system training that requires a few minutes, and its adaptability.

Within this paper, a review of the literature will be presented, in which terms related to product non-conformity itself, identification and classification, and non-conformity management methods will be defined. The technologies applied within this study as well as the system developed by this study

for the purposes of identifying product non-conformities, which arise from the needs that are a consequence of real problems in the manufacturing industry.

## **2. Literature review**

### **2.1. Non-compliance**

A non-compliant product is any product that deviates from the quality defined by the standard, that is, from the requirements of the customer or user of the product or service. Observed from the aspect of non-conformity of the product that can occur during its production itself, it can be concluded that a larger number of non-conformities or deviations from quality requirements can be detected on one product at some point. The increased production of non-compliant products directly affects the company's profit, primarily through increased losses, among the biggest losses are certainly the raw materials needed for the production of products, additional time spent by employees, additional energy (Liepiņa et al., 2014;). In order for the company not to get into a situation that could endanger its business, it is necessary to adhere to the quality of the product defined by the standard, which further leads to the need for quality control, i.e. continuous checks to see if there are non-compliant products in production (Powell et al., 2021; ). It certainly does not mean that even if a product's non-conformity is observed, it cannot be used further, in some cases it is possible to refine it, and that is if it is a minor non-conformity, while in the case of a major non-conformity, the product is declared scrap and as such cannot continue the further process ( Hoyle 2009). Of course, if it is possible to finish the product, it is further sent to the finishing process, but this can significantly affect the price of its production (Hoyle 2009).

## **2.2. Identifying non-conforming products in the industry**

The identification of non-conforming products within the manufacturing industry can be seen as a process of determining deviations from the product quality requirements of a company, and it can happen on the production machine itself, the production line, or on the packaging of the product as a final process during the life cycle of the production of a product (Donauer et al., 2015; Powell et al., 2021;). Although the process was successfully implemented and the product nonconformity was identified, the identification of the cause that led to the nonconformity is also of great importance, preventing the cause that led to the nonconformity directly affects the further flow of production (Ligarski 2012; Powell et al., 2021 ;). Deviations can be in the form of surface inconsistencies or inconsistencies that can appear in the structure of the material, which leads to different methods of identifying inconsistencies and to different technologies that can be used in the process of identifying inconsistencies (Koucha et al., 2021;). Successful and timely identification of non-compliant products directly affects the reduction of scrap, savings in production time, and losses that occur due to product processing (Koucha et al., 2021;).

## **2.3. Methods of identification of product non-conformity**

The basic methods of identification of inconsistencies refer to surface inconsistencies and internal inconsistencies, which are based on the structure of the material. External defects are those located on the surface of the product, most often caused by machine failure or carelessness of employees, and refer to minor damage such as scratches, paint, text, etc. While internal defects are mainly based on the discovery of trapped air during metal casting, which can

later result in cracking of the product. The methods of detecting internal non-conformities that are most often applied today are radiation methods, ultrasound methods (Yang et al., 2020). Using ultrasonic methods based on the propagation of the ultrasonic wave, it is possible to conclude in which region the inconsistencies are found, as well as the order of their magnitude (Ha et al., 2021). The beam-based method uses a beam that is passed through the material and thus the location of the defect as well as the size can be obtained (Cacace et al., 2021). While the methods of detecting surface non-conformities in small and medium-sized companies are mostly based on manual control, that is, they depend on the employee and on the basis of his knowledge and experience as well as his ability to visually recognize the defect. When it is necessary to control product dimensions or centricity, there are manual tools that can be applied that depend on the employee. The application of modern technologies such as machine vision applied for visual control brings with it a number of advantages, shorter data processing time, timeliness, accuracy (Yu et al., 2019). Of course, machine vision depends on the quality of the equipment, the algorithm used to select and recognize non-conformities, but on the other hand, after installing the system, it is independent, that is, it does not depend on the employee and his knowledge and experience, it provides data in real time (Oqaidi et al., 2021, Sivkov et al., 2020, Steenkamp et al., 2017, Chai et al., 2021). Certainly with the application of computer vision and within Industry 4.0. technologies such as deep learning and artificial intelligence are also applied for faster and more efficient non-conformity selection as well as event prediction based on system experience, cloud data storage systems, IIOT (industrial internet of things) is applied for machine control based on defined non-conformity, industrial robots as well as

industrial production lines, (Cronin et al., 2021, Julian oks et al., 2021, Khan et al., 2020, Shavetov et al., 2019, Oqaidi et al., 2021, Sivkov et al., 2020, Steenkamp et al., 2017, Chai et al., 2021).

#### **2.4. Classification of non-conformities**

As the level of non-conformity of the product can differ by several different factors, it can be divided into minor non-conformities, major non-conformities and critical non-conformities (Monteiro et al., 2019; Powell et al., 2021;). Minor non-conformities are noticeable, but the product as such can be found on the market at lower prices with an indication that it deviates from the standard (Gamme et al., 2019;). Greater product non-conformity requires product rework after which the product can be forwarded to the market (Chiu et al., 2018;). Critical non-conformance represents deviations from the requirements that affect the functionality of the product, which automatically means that it cannot be used as such (Hoyle 2009). Product non-conformity can occur for several reasons, the most common of which is due to the failure of the production machine, deviation of the quality of the material from which the product is made, carelessness of employees (Chiu et al., 2018;). Product non-conformity can be expressed in several ways, the basic way is external and internal non-conformity (Chiu et al., 2018; Monteiro et al., 2019;). External non-conformity is a deviation that is visible, it is most often damage on the surface of the product or semi-finished product in the form of scratches, deviation of shape, dimensions, text, color (Monteiro et al., 2019;). While the internal non-conformity refers to the structure of the material, if it is metal casting or plastic injection, there may be air trapped in the product itself (Gamme et al., 2019;). In order to prevent the production of non-compliant products, it is necessary to react in time, that is, if an employee notices the

production of non-compliant products that occurred as a result of a machine failure, it is necessary to stop the further flow of production. It is necessary to classify non-conforming products according to the degree of non-conformity and, based on the data, proceed further in accordance with the company's policy (Gamme et al., 2019;). After the non-conformity identification process, it is necessary to mark the non-conforming products based on the classification, which refers to products that can be processed, can be sold as such, but with a note, products that are sent to scrap (Monteiro et al., 2019; Powell et al. ., 2021;). Successful classification of non-conforming products can prevent the appearance of non-conforming products on the market, which significantly affects the company's business. Marking of non-compliant products after classification should be a defined process and easy to learn for employees, so that based on a successful classification, the products will be passed on to the production flow in accordance with the performed classification.

#### **2.5. Management of non-conformities**

Successful management of non-conforming products is the basis of a company's successful production. In order to successfully manage non-compliant products, it is necessary to define product control intervals, ways of marking non-compliant products, and procedures for disposing of non-compliant products. Control intervals are directly related to the type of production, whether it is serial mass or individual, as well as by top management (Hoyle 2009). After the detection of a non-conforming product, and depending on the level of non-conformity, it is necessary to mark the product in an adequate way if it is a question of critical non-conformity, after which the product is declared as scrap and as such is further sent for destruction, in the

case of major or minor non-conformity, if it is possible, it is necessary to refine the product mark the product and pass it on for further processing (Hoyle 2009; Powell et al., 2021;). The marking of non-conforming products is one of the important processes, since on the basis of the marked products, the procedure is followed, the marking differs from company to company, mostly companies practice to have an internal way of marking (Hoyle 2009).

### **2.6. Application of computer vision in the quality control process**

Computer vision can provide a wider range of data in terms of quality control, positioning of robots in space, control of production lines as well as the products themselves, object recognition, barcode scanning (Louw et al., 2019). The quality control process can be observed in several ways, depending on the production itself, i.e. what needs to be controlled, mainly the color of the product, the text or stamp on the product that is stamped, dimensional control, quality control of the object's surface, i.e. whether there are visible damages on the surface such as scratches or in the process of forming the sheet whether it contains all the necessary openings. Also when it comes to monotonous tasks such as comparing two objects or sorting both on the industrial machine itself and on the production line, computer vision is imposed as a good technology for the mentioned application. Certainly, when it comes to precise profile measurements, which require a lot of time, the process can be accelerated with the application of computer vision. Monitoring of products throughout the entire technological process of production or within a certain technological process.

### **2.7. Industry 4.0.**

By applying Industry 4.0 technologies. in the process of identifying product non-conformities, significant advantages can be achieved compared to manual identification (Bigliardi et al., 2020; Horváth et al., 2019). All this affects the speed of production, product quality, timeliness of data, availability of data, accuracy (Culot et al., 2020). The most important technologies of industry 4.0 that are applied in the process of non-conformity identification are: computer vision, IIOT (Industrial Internet of things), deep learning, neural networks, databases, internet networks, microcontroller platforms, programmable logic controller, cloud, embedded systems, sensor systems, distributed systems (Albers et al., 2016, Bal et al., 2019; Müller 2019; Tupa et al., 2017, Mijailović et al., 2020).

### **2.8. Cloud**

The storage of real-time data collected from the industry in a database that can be accessed independently of the platform or operating system is called the cloud. These systems represent one of the most important tools for the successful implementation of Industry 4.0. (Lane et al., 2016). The application of cloud systems in relation to traditional databases has a number of advantages, the most significant of which are access in real time, it lowers the necessary funds related to the maintenance of the database and the hardware part (Kolesnyk et al., 2021; Mijailović et al., 2018). In the case of the application of some other databases that require hardware systems for storing large amounts of data, they would be within the manufacturing industry (Lane et al., 2016; Murugaiyan et al., 2020), which actually represents a number of disadvantages of such a system. While in the case of cloud system application, all data is located in one place that is always available,

with the fact that the lack of such systems can represent an internet connection (Lane et al., 2016).

### 3. Case study

This paper presents a system developed for the identification of non-conforming products or semi-products, based on the application of computer vision. In the process of identifying non-compliant products, the system, in addition to data acquisition, performs the process of detecting contours based on circles. As it is often the case that in industry, during the production process, the product contains openings for screw connections or technological openings that are further important for the product assembly process, hence the need for the development of such a system. Also the application of this system that is imposed is the product assembly process where the identification of screws can be done, it can also be applied for product selection. Based on the use of the Hough transformation, it detects circles on the semi-finished product, preventing further operation of the machine if the lack of one or more circles is identified. The system was developed to work in real time, where data is stored on the cloud, providing the possibility of accessing data in real time. Certainly, the advantages of using this system are reflected in speed, flexibility, reduction of the number of non-compliant products, precision.

#### 3.1. System software

When it comes to starting the system for the first time, it is necessary to place the hardware on the corresponding production machine, after checking the system can be started. After the first start of the system, it can work independently, which makes the application of this technology an advantage over traditional ways of identifying non-compliant products. When the system is

started, images are acquired using computer vision and the OpenCV library, then the collected data are processed using Hough's transformation, and the output of the system is data related to the number of identified circles as well as the number of compliant or non-compliant products. It is also possible to define conditions related to the number of identified circles, after obtaining the specified data they are stored on the cloud in the specific case ThingSpeak was used. The mentioned process is executed in real time, where the total time of the algorithm is 0.35 seconds for one image, which is certainly faster than the system requirements, that is, from the production machine and its process of producing one product. Certainly one of the important features of this system is adaptability, it can be moved from one production machine to another and continue working without interruption. Algorithm performance tests were performed within the premises of the university, laboratory of the quality center. In Figure 1, you can see an example of a semi-finished product that has circles on it that refer to twisted screws.

**Figure 1.** Example of a semi-finished product with both screws

Source: Author

As can be seen in Figure 1, the semi-finished product contains 2 screws that were detected using the developed system. Figure 2 shows the result of the algorithm.

```
The first contour is the screw: 39 px.  
The second contour is the screw: 39 px.
```

**Figure 2.** Result of the semi-finished algorithm with both screws

Source: Author

Based on the results of the system algorithm, which are shown in Figure 2, it can be seen that the product is compliant. In Figure 3, you can see the non-compliant semi-product.

**Figure 3.** Non-compliant semi-finished product  
Source: Author

Based on Figure 3, it can be concluded that one screw is missing from the semi-finished product, which can also be seen based on the results of the algorithm shown in Figure 4.

The first contour is the hole for the screw: 35 px.  
The second contour is the screw: 39 px.

**Figure 4.** Inconsistent product of algorithm results  
Source: Author

As can be seen in Figure 4, the product is non-conforming, it does not have one of the two screws. The presented data is stored on the cloud system within this system thingspeak cloud was used, an example of the stored data collected by this system can be seen in Figure 5.

**Figure 5.** Data stored in the cloud  
Source: Author

We can additionally process and display data stored in the cloud in several ways, the advantage of cloud data is its availability.

## 4. Discussion

The focus of the system developed in this work is on the process of identifying product non-conformities with the use of modern technologies that involve the application of computer vision. After the implementation of the system in the production industry, it brings a number of benefits compared to the traditional ways of identifying non-compliant products. Some of the advantages are reflected in the speed, accuracy, flexibility, independence of the developed system. Traditional ways of identifying non-conformities involve the interaction of an employee, i.e. the engagement of employees from the product quality sector, where there are a number of limitations and in terms of the time necessary to identify non-conformities if it is a serial production or several production machines, the time needed to form a report or the reaction that would stop the further flow of production if there is an increased number of product non-conformities. While in the case of the application of the system developed in this work, we receive the data in real time, the reaction of the system is also in real time, we can create reports, the data is stored in the cloud and can be accessed from all platforms and operating systems and further processed. The shortcoming of this system can be seen from the aspect that it was developed for use on one production machine, while a quality expert can observe several different machines as well as different types of non-conformities. Certainly, the use of this system and timely reaction affects the further flow of production and the reduction of non-compliant products.

## 5. Conclusion

The system developed by this case study represents a solution that should reduce the production of non-conforming products created in production, most often caused by a machine failure or error, thus satisfying the initial goal of the study. The increased number of non-compliant products directly affects customer satisfaction as well as costs, which certainly represents another goal for the development of this system. Timely reaction of the system is essential in terms of stopping the further flow of production of non-conforming products, which directly affects the production time.

The results of the study, which were stored on the cloud, were presented. The system has

limitations related to the application itself, the developed system is used to identify contours that represent circles, which means that it cannot be used for contours of other shapes. Certainly the developed system satisfies the initial goal where the focus was on the detection of contours representing circles. This study presents a unique solution for the application of software used for identification, which is based on the implementation of the Hough transform and the training of the system, which involves defining the basic parameters related to the number of contours and their size. Further directions of this study will go towards the development of a system that will be able to detect a larger number of different contours on one product.

## SIMULATION OF LIQUEFACTION OF NITROGEN RICH GASEOUS EMISSIONS FROM THE OXYGEN PRODUCTION PLANT

**Abstract:** Liquid  $N_2$  attained extensive applications in the fields of refrigeration, medical, constructional and chemical industries. Oxygen production plant in Orotta Hospital, Eritrea assessed with  $156.6 \text{ Sm}^3/\text{hr}$  of waste  $N_2$  gases that contains 96.4 % (vol) of  $N_2$ . Thus this work focused on the liquefaction of such waste gases employing Precooled Linde-Hampson and Kapitza's cycles in aspen HYSYS®. Specific energy requirements assessed initially for open and closed loop models and noted higher rates in all open loop cycles examined. Highest Pressure and the Lowest Temperature adjudge the extent of  $N_2$  liquefaction. Optimal liquefaction of Pure  $N_2$  at 150 atm of CDP and  $-115.2^\circ\text{C}$  of LCT in PLHC system yielded a liquid of  $156.6 \text{ Sm}^3/\text{hr}$  at the expense of 4195.4 kJ/L of energy while the waste  $N_2$  gases liquefies at 400 atm of CDP and  $-107.2^\circ\text{C}$  of LCT with 68.1 % of excess energy consumption. Pure  $N_2$  liquefaction in KC at 40 atm and  $-171.2^\circ\text{C}$  resulted in 0.148 liquid fraction at the energy cost of 3719 kJ/L whereas the optimal liquid fraction of 0.1488 and  $\text{COP}_{\text{act}}$  of 0.8404 were derived from the liquefaction of waste  $N_2$  gases at a CDP of 40 atm and LCT of  $-162.5^\circ\text{C}$ . However, Kapitza's system has proven to be more attractive than PLHC in terms of energy savings although both models produce similar products.

### 1. Introduction

Liquefaction of gases has been practiced for several years and become a key branch of cryogenics for wide applications including commercial liquid gas production for easy storage, handling, transportation and potent applications in cryogenic engineering that meant to design and maintain systems or components at lower temperature. Gases can be liquefied either by cooling or by applying

high pressures or by combined effect of both. Liquefied gases have prominent role in industrial applications. Liquid forms of nitrogen, ammonia and  $\text{SO}_2$  can be used as refrigerants, liquid  $\text{CO}_2$  finds application in soda fountains, liquid chlorine has importance in bleaching and disinfectant purposes, liquid air served as best source of  $\text{O}_2$  in rockets and jet-propelled planes, liquid helium has driven the development of space research and liquid hydrogen acquired

attention for the significant applications in nuclear weapons development and rocket propulsion [Narayanan. K.V 2011]. However, permanent gases such as N<sub>2</sub>, H<sub>2</sub>, Ar or O<sub>2</sub> usually possess very small intermolecular forces of attraction and cannot be liquefied easily due to their lower critical temperature (T<sub>c</sub>) while the gases for which the intermolecular forces are larger such as NH<sub>3</sub>, SO<sub>2</sub> and H<sub>2</sub>O have high value of T<sub>c</sub> and can be easily liquefied.

Nitrogen(N<sub>2</sub>) is a diatomic chemical element available plentifully in atmospheric air and exist in the gaseous state at ambient conditions whereas liquid nitrogen is a cryogenic liquid obtained by the liquefaction process at a very low temperature of -196°C. Liquid nitrogen is odorless, colourless, non-reactive and non-flammable liquid majorly produced by air separation techniques such as cryogenic distillation and pressure swing adsorption (PSA). Liquid nitrogen has been applied as a coolant in food preservation, transportation and desserts making. In medicine it is used as a refrigerant in cryobanks to preserve biological cellular materials such as reproductive cells that include sperm & egg, semen, blood and other tissue samples. Furthermore, liquid nitrogen is employed in dermatology for freezing and preventing the growth of precancers, benign growths and skin cancers by spraying or applying liquid nitrogen with a cotton swab. In the field of construction, the demand of liquid nitrogen has been rising due to its applications in hardening of concrete at accelerated rates. In addition, liquid nitrogen covers the other industrial applications such as metal hardening, temporary ground freezing, rubber removal and pipe freezing. Presently, modern electronics incorporated with semiconductors, which enable conductivity between metals and insulators. As the supercomputers run highly complex calculations and perform millions of functions, semiconductors usually subjected

to higher temperature that need to be maintained at constant temperature and liquid nitrogen has become one of the top choices to control the temperature. Thus, liquid nitrogen market valued globally at USD 15.98 billion in 2021 and predicted to reach USD 23.61 billion by 2029, registering a CAGR of 5.00% during the forecast period of 2022-2029 [DBMR 2023].

Adversely, liquid nitrogen has a high liquid-gas expansion ratio of 1:694 at room temperature, causes a tremendous force generation if it vaporized rapidly in an enclosed container and it can destruct the surroundings and harm to humans as well [GVRR 2023]. In general, cryogenic liquid gases are highly hazardous and causes cold burns if it comes to contact with biological species including humans. Mishandling of liquid nitrogen could lead to spillage and pose to significant threats to the surrounded people. Such probable hazardous effects in handling procedures anticipated to restrain market growth over the forecast period. However, by following the safety guidelines properly and maintaining necessary personal protective devices, such hazards could be prevented.

Cryogenic distillation is a dominant technology in the production of liquefied industrial gases coupled with low investment and few utility consumption and today it accounts for 65-70% of total nitrogen production [SRI Consulting 2023]. Nevertheless, pressure swing adsorption (PSA) technology is expected to lead in air separation applications without liquefaction [GVRR 2023]. In addition, in-situ applications of gases such as oxygen and nitrogen demand PSA technology that makes favor with little investments and avoidance of hazards in handling liquefied gases along portable plant features. Unfortunately, in many plants when PSA technology meant for the production of oxygen, nitrogen rich gaseous streams are simply emitted into atmosphere. Instead such waste N<sub>2</sub> rich gases

can be liquefied to facilitate the benefit of available liquid nitrogen in the local market.

Several cryogenic cycles can be employed in liquefaction of gases such as Linde Hampson cycle, Claude's cycle, Kapitza's cycle and Collins liquefaction cycles [Yilmaz.C et al 2019, Saini. A et al 2019]. Many different methods can be adopted in cooling of gases to liquefy including Faraday's principle, adiabatic expansion, Linde's and Claude's methods [Schimd. J 2023, Nag. P. K. 2006]. The effect of cooling can be facilitated by expanding high pressure gases to lower pressure in Faraday's method to liquefy the gases that possess critical temperature above or just below the ambient conditions. Adiabatic expansion featured by altering pressure at constant total heat of the system, which causes gaseous molecules to be liquefied. Linde's method includes a Joule-Thompson's valve that reduces pressure and cools the gas to partially liquefy. Non-liquefied gases can be recycled back along with fresh feed to improve the yield of liquid fraction. However, the Claude's method is a modified version of Linde's practice and specially facilitated to extract some amount of work while gases expand to lower pressures. In addition, Kapitza's cycle and Collins cycles follows Claude's cycle with some changes in number of heat exchangers used for cooling and the choice high pressure stream that allows to produce some work.

Liquefaction of nitrogen from air separation has been modeled and studied by several people [Yilmaz.C et al 2019, Saini. A et al 2019]. However, in the present work, Precooled Linde-Hampson's [Yilamz.C et al 2019, Schimdt.J. 2023] and Modified Claude's cycle (Kapitza's Cycle) [Schmidt.J 2023, Nag.P.K 2006] have been adopted to study the production of liquid nitrogen using waste N<sub>2</sub> rich gases that are emitted from PSA plant operating for air separation. The systems are modeled for pure N<sub>2</sub> and waste N<sub>2</sub> gaseous feedstocks in Aspen HYSYS® to identify the effect of presence of impurities

and change in pressure on liquefaction rate, cooling temperature patterns and specific energy consumption. Energy consumptions are compared without recycle and with recycle of gaseous fractions in both Linde's and Claude's methods.

### 1.1 Oxygen Production Plant of Orotta Hospital (OPPOH)

Orotta Hospital is the nationalized medical centre that provide services in most specialized treatments in Eritrea and always in need of oxygen for life supporting systems. The Orotta Hospital has established its own oxygen plant that utilizes air and produces oxygen using pressure swing adsorption (PSA) technology. In general, PSA devices take fresh air and stores in a collector tank and then it allowed through pre-filters for the removal of mist or particulate matter (PM).

Later the pre-screened air stored in the tank 1 as depicted in figure 1. and passed through second set of filters which are packed with zeolite and activated by the chemicals such as aluminium oxide that captures N<sub>2</sub> with dipole creation and allows O<sub>2</sub> to pass through at an elevated minimum pressure of 1.5 atm. After a certain volume of air separated the zeolite bed gets saturated with N<sub>2</sub> absorption, which requires periodic regeneration that should be facilitated by dropping pressure back to atmospheric conditions [TPPL 2023, Rao & Muller 2007]. PSA devices are mainly preferred to generate oxygen in place where it can be utilized to avoid transportation risks although it produces O<sub>2</sub> of less purity and portable capacities, thus OPPOH produces O<sub>2</sub> of 92% (volume) purity in addition to other components of 7% N<sub>2</sub> and 1% Ar at a rate of 37 N m<sup>3</sup>/hr.

Since the OPPOH is not meant to recover any N<sub>2</sub> that is released during air separation, huge amount of N<sub>2</sub> rich waste gases are

emitted into the atmosphere. So far in Eritrea there is no local production of liquid N<sub>2</sub> to support cryogenic refrigeration systems applicable for both industrial and medical

applications. Thus the estimated rate of N<sub>2</sub> rich emissions of 156.6 S m<sup>3</sup>/hr with 96.4% of N<sub>2</sub> content attracts to utilize by means of liquefaction.

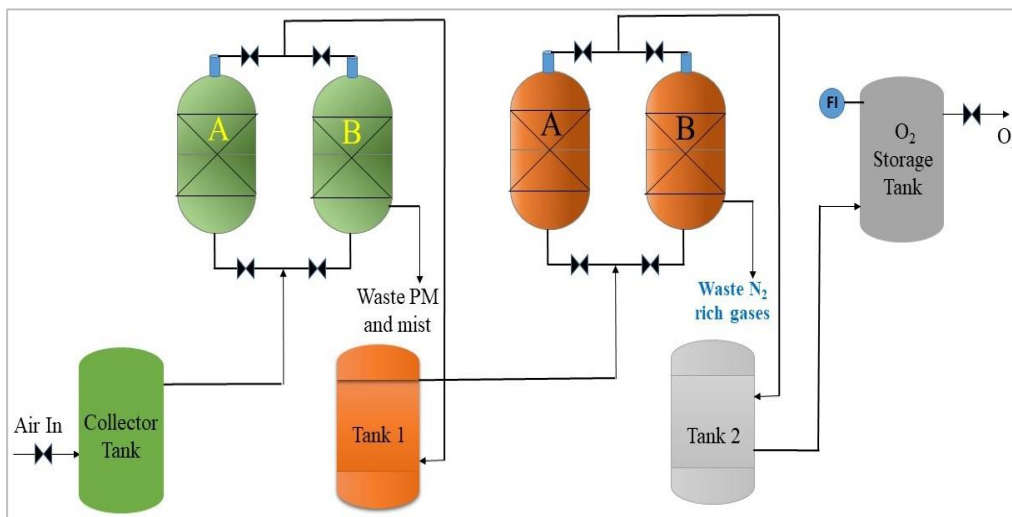

Figure 1. Pressure Swing Adsorption(PSA) Process for O<sub>2</sub> Production in OPPOH

## 2. Materials & Methods

### 2.1 Feedstock Materials

Waste N<sub>2</sub> rich gases at a rate of 156.6 S m<sup>3</sup>/hr with the composition shown in the Table1. and Pure N<sub>2</sub> has been considered for the comparative study in both Linde-Hampson and Kapitza's cryogenic cycles.

**Table 1.** Chemical composition of Waste N<sub>2</sub> gaseous resources from OPPOH [Personal Communication 2023]

Component	Volume (%)
N <sub>2</sub>	96.4
O <sub>2</sub>	2.62
Ar	0.91
CO <sub>2</sub>	0.07

## 2.2 Methods

### 2.2.1 Precooled Linde Hampson's Method

The precooled Linde Hampson's cycle has been adapted to develop the liquefaction process [Yilmaz.C et al 2019]. The Feed gas first compressed to the desired pressure level that causes significant rise in temperature which must be reduced in a cooler to attain ambient temperature of 25 °C as shown in figure 2. Then the pressurized gas passed through a heat exchanger where its further cooled by utilizing the cold recycled gaseous streams from the separator. Later the gasses are allowed to get through a Joule-Thompson's valve in which highly compressed gas throttled to atmospheric pressure adiabatically that experiences drastic drop in temperature and a fraction of liquid gets separated from the cold gases. Thus the extremely colder gases could be

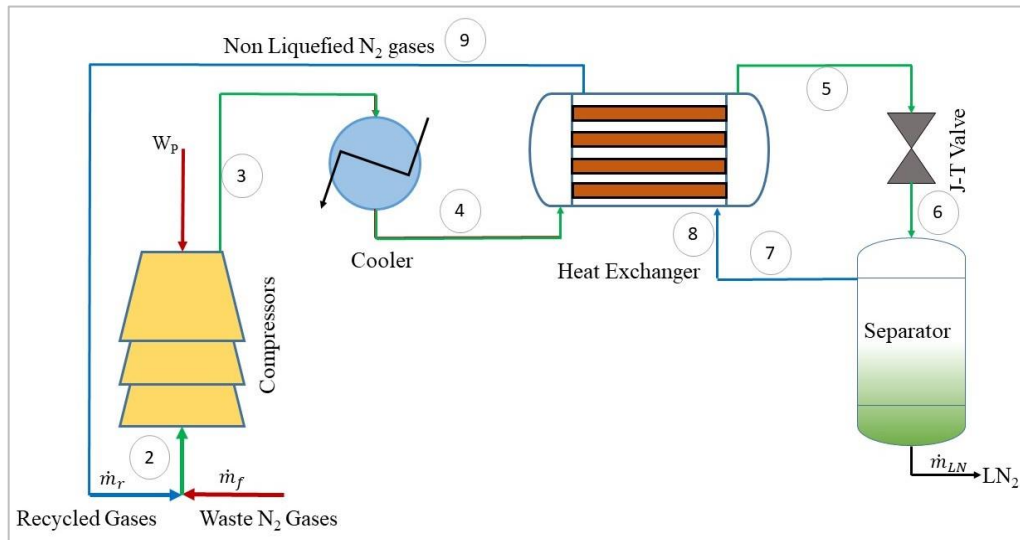

recycled back in to the process through a heat exchanger and mixed with fresh feed to undergo for compression. The gas compressed to a pressure range of 100 atm - 500 atm to determine the optimized liquid yield. If r is refrigerant or the recycled gases that are utilized as refrigerant in the heat exchanger, the fraction of gases that are liquefied can be calculated in terms of

corresponding stream enthalpies using the following relation

$$y = \frac{h_4 - h_9}{h_{LN} - h_9} = \frac{\dot{m}_{LN}}{\dot{m}_f + \dot{m}_r}$$

Where  $\dot{m}_{LN}$ ,  $\dot{m}_f$  and  $\dot{m}_r$  represents the volumetric flow rates of liquid nitrogen, fresh feed and recycled feeds respectively.

**Figure 2.** Precooled Linde-Hampson Cycle for the Liquefaction of waste N<sub>2</sub> gases

The energy balance for compressor can be written in terms of enthalpies ( $h$ ) and entropies ( $s$ ) of the corresponding streams as

$$W_p = (h_3 - h_2) - T_2(s_3 - s_2)$$

The actual coefficient of performance of the overall cycle can be expressed as

$$\begin{aligned} COP_{act} &= \frac{\text{heat transferred per unit mass of gas}}{\text{Total energy input of the system}} \\ &= \frac{Q_L}{W_{in}} = \frac{(h_3 - h_2) + r(h_8 - h_9)}{(h_3 - h_2) - T_2(s_3 - s_2) - r(h_8 - h_9)} \end{aligned}$$

Where  $r = \frac{\dot{m}_r}{\dot{m}_f + \dot{m}_r}$ , the fraction of recycled stream

And the energy consumption per L of liquid nitrogen ( $\dot{E}$ ) is estimated according to

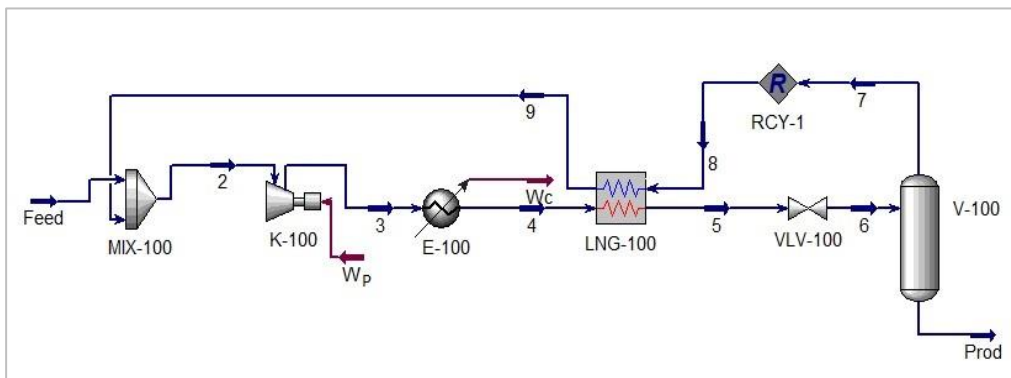

$$\dot{E} = \frac{W_p}{Y} \quad \left( \frac{kJ}{l} \right)$$

Where  $W_p$  is the power consumed for the compression in kW and  $Y$  is the amount of liquefied gases in liter/sec.

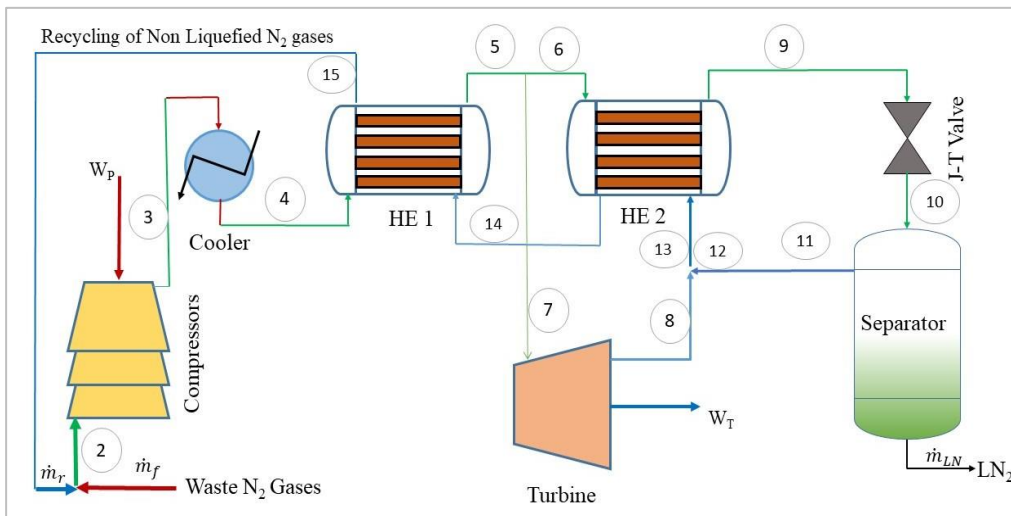

**2.2.2 Aspen HYSYS® Model for Precooled Linde-Hampson Cycle**

Pure nitrogen and other impurities such as oxygen, argon and CO<sub>2</sub> are added to component list and Peng-Robinson fluid package opted for the estimation of thermodynamic properties and other system calculations. The Linde's cycle is modelled as shown in figure 3 using the objects such as a mixer (MIX-100) to blend fresh feed with recycled one, compressor (K-100) to increase pressure to the desired level, cooler (E-100) to bring down the temperature of high pressure gases to ambient conditions followed by a cryogenic heat exchanger (LNG-100) to decrease the temperature of gases to further lower levels using cold gases that are recycled from the separator (V-100). Joule-Thompson's expansion valve (VLV-100) applied to decrease pressure to atmospheric levels at where the separation of liquid and gases takes place. 75% of isentropic efficiency for compressor is assumed in simulating the model.

(E-100) to bring down the temperature of high pressure gases to ambient conditions followed by a cryogenic heat exchanger (LNG-100) to decrease the temperature of gases to further lower levels using cold gases that are recycled from the separator (V-100). Joule-Thompson's expansion valve (VLV-100) applied to decrease pressure to atmospheric levels at where the separation of liquid and gases takes place. 75% of isentropic efficiency for compressor is assumed in simulating the model.

**Figure 3.** Aspen HYSYS® model for Waste N<sub>2</sub> gases liquefaction using Linde Hampson's cycle.

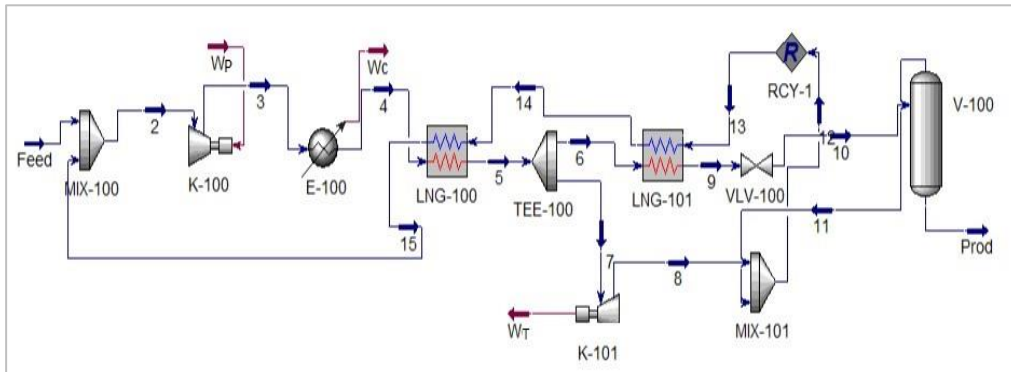

**Figure 4.** Schematic representation of modified Claude's cycle (Kapitza's Cycle)

### 2.2.3 Modified Claude's (Kapitza's Cycle) Method [Yilmaz.C et al 2019]

In the present work, modified Claude's cycle known as Kapitza's cycle has been considered to study the liquefaction of waste N<sub>2</sub> gases. As shown in figure 4. Fresh feed along with recycled one enters into the compressors to achieve desired pressure level of 40 atm and then it is cooled to ambient temperature of 25°C and subsequently cooled to cryogenic conditions in the heat exchangers 1 and 2 (HE1 & HE2). But, before the stream is allowed for

further cooling in HE2, a portion of gas is diverted to a turbine to produce some work and then it allowed to join with non-liquefied gases to recycle back into the process through HE2 & HE1.

Since J-T valve is the most economical to expand the gases to atmospheric conditions, it has applied to cool the gases and separate liquefied gases from the non-liquefied. If  $x$  is the fraction of total gases that are diverted to the expander and an isentropic work produced by the turbine then the heat balance on turbine

**Figure 5.** Aspen HYSYS® model for Waste N<sub>2</sub> gases liquefaction using Kapitza's cycle.

can be written as

$$h_T = h_5 - \eta_T(h_5 - h_8)$$

The work produced by the turbine can be estimated by the following relation

$$W_T = h_5 - h_T = \dot{m}_8(h_8 - h_5)$$

The net work done in the entire Kapitza's cycle is expressed as

$$\begin{aligned} W_{net} &= W_p - W_T \\ &= [(h_2 - h_3) - T_2(s_2 - s_3)] - z(h_5 - h_T) \end{aligned}$$

The yield of liquid fraction produced from the Kapitza's cycle given by

$$y = \frac{x(h_8 - h_5) + (h_4 - h_{15})}{h_{LN} - h_{15}}$$

Where  $x = \dot{m}_8/\dot{m}_4$ , the fraction of gas that is diverted to expander and  $y = \dot{m}_{LN}/\dot{m}_4$ , the fraction of gas that is liquefied.

The coefficient of performance of the cycle can be calculated as

$$\begin{aligned} COP_{act} &= \frac{\text{heat transferred per unit mass of gas}}{\text{Net Power Consumed in the cycle}} \\ &= \frac{(h_2 - h_3) + z(h_5 - h_T)}{[(h_2 - h_3) - T_2(s_2 - s_3)] - z(h_5 - h_T)} \end{aligned}$$

And the energy consumption per L of liquid

nitrogen ( $\dot{E}$ ) is estimated according to

$$\dot{E} = \frac{W_{net}}{Y} \left( \frac{kJ}{l} \right)$$

Where  $W_{net}$  is the net power consumed in the entire cycle in kW and  $Y$  is the amount of liquefied gases in liter/sec.

### 2.2.4 Aspen HYSYS® Model for Kapitza's Cycle

Following the same initial steps as the Linde's cycle, Pure nitrogen and other impurities such as oxygen, argon and CO<sub>2</sub> are added to component list and Peng-Robinson fluid package selected for the estimation of thermodynamic properties and other system calculations. The Claude's cycle is modelled as shown in figure 5. That includes two mixers (MIX-100, 101), compressor (K-100), cooler (E-100), two heat exchangers (LNG-100, 101), a splitter (TEE-100), turbine (K-101), a J-T valve (VLV-100), a separator (V-100) and a recycle stream (RCY-1). A turbine of 75% isentropic efficiency has been considered to produce some work from 80% of total gas stream that is diverted before it enters into the second heat exchanger (LNG-101).

## 3. Results and Discussion

The performance of gas liquefaction cycle depends on the parameters such as feed composition, compressor discharge pressure, temperature approaches in the heat exchangers, lowest cooling temperature, number of heat exchangers, the presence of turbines to extract work and gas fraction diverted to expander in case of Claude's cycle. In the present study, the performance of Precooled Linde-Hampson cycle and modified Claude's cycle were tested with pure N<sub>2</sub> and waste N<sub>2</sub> streams, with and without recycling of non-liquefied gases to examine several performance indicators such as liquid yield, actual COP and energy consumptions per liter of liquid nitrogen

produced.

### 3.1 Liquefaction of Pure N<sub>2</sub> Gases by Precooled Linde-Hampson Cycle (PLHC)

Initially the feed considered at atmospheric pressure and 25 °C of temperature, then it allowed through a compressor with a discharge pressure of 100 atm to examine the possibility of liquefaction by changing the lower cooling temperature ( $T_5$  in figure 3) with and without recycling non-liquefied gases to determine maximum liquid yield and optimal energy consumption. The open loop (without recycle) precooled Linde's machine investigated to find the optimal LCT of 158 K in the heat exchanger at where the highest liquid yield of 8.091 Sm<sup>3</sup>/hr was recorded for a pure N<sub>2</sub> feed rate of 156.6 Sm<sup>3</sup>/hr. The temperature cross noted in the heat exchanger beyond 158 K on the lower end whereas on the higher end, it was not producing any liquid product beyond 162 K as depicted in the figure 6.

A similar kind of study for closed loop (with recycle) precooled Linde-Hampson cycle was performed at the optimal conditions derived based on the results obtained from the open loop machine analysis.

**Figure 6.** The effect of LCT on Pure N<sub>2</sub> liquefaction in open loop PLHC machine

**Figure 7.** The effect of CDP on Pure N<sub>2</sub> liquefaction in open loop Precooled Linde's cycle

At the LCT of 158K, closed loop system has provided 156.6 Sm<sup>3</sup>/hr of liquid N<sub>2</sub> and the relative energy consumption per L of liquid N<sub>2</sub> has reduced significantly when compared with the open loop cycle. The specific energy consumption of 6878.16 kJ/L was determined in the precooled Linde's cycle while it was calculated as 17259.17 kJ/L for the open loop cycle.

### 3.2 The Effect of Compressor Discharge Pressure (CDP) on Pure N<sub>2</sub> liquefaction

Firstly, at a fixed LCT of 158 K, the effect of changing CDP was tested in between 100 atm - 300 atm to understand the variation in the liquid yield (y) from the open loop precooled Linde's cycle as shown in figure7.

**Table 2.** The effect of discharge pressure on liquid yield and its N<sub>2</sub> composition for the liquefaction of waste N<sub>2</sub> gases using open loop PLHC.

CDP atm	LCT °C	Liquid Yield (y), Sm <sup>3</sup> /hr	Composition of N <sub>2</sub> in the liquid (vol fraction)
150	-108.2	11.12	0.8936
200	-105.2	12.61	0.8964
300	-103.2	13.82	0.8984
400	-106.2	17.12	0.9033
500	-108.2	16.86	0.9029

**Table 3.** Comparison of Liquefaction of waste N<sub>2</sub> with Open loop and Closed loop PLHC systems

Parameter	Open loop PLHC	Closed loop PLHC
CDP (atm)	400	400
LCT (°C)	-106.2	-107.2
Liquid yield (Sm <sup>3</sup> /hr)	17.12	168.2
N <sub>2</sub> Composition (vol fraction)	0.9033	0.9630
Energy consumption (kJ/L)	13543.6	13148.5

**Table 4.** Comparison of Liquefaction of Pure N<sub>2</sub> gases with Waste N<sub>2</sub> gases using PLHC system.

Parameter	Liquefaction of Pure N <sub>2</sub> gases using PLHC at optimal conditions	Liquefaction of Waste N <sub>2</sub> gases using PLHC at optimal conditions
CDP (atm)	150	400
LCT (°C)	-115.2	-107.2
Liquid yield (Sm <sup>3</sup> /hr)	156.6	168.2
N <sub>2</sub> Composition (volume fraction)	1.00	0.9630
Energy consumption (kJ/L)	4195.4	13148.5

A step change of 50 atm in CDP was applied, as the pressure increases from 100 – 150 atm, there was a noticeable change in the liquid yield from 8.091-21.47 Sm<sup>3</sup>/hr when compared with farther step changes in CDP. It was also noted that the yield of liquefied gases increases with increase in CDP while the consumption of the power for compression increases. As mentioned in reference [APCI 2019], pure nitrogen liquefaction, J-T refrigerator working pressure should be in the range of 10-20 MPa, it was validated in between 100-150 atm, to obtain an optimal power consumption per L of liquid N<sub>2</sub> at 150 atm as 7572.1 kJ by the open loop liquefaction. Similar optimal conditions of 158 K, 150 atm of LCT and CDP applied respectively in PLHC (Closed-loop system) and a liquid yield of 156.6 Sm<sup>3</sup>/hr measured with a specific power consumption of 4195.4 kJ/L, which is substantially lower than the case of open loop system. In contrast to the results obtained by the reference [Prasad.S 2009], liquid yield has increased with increase in pressure from 100-300 atm but to avoid pinch point issues it was studied up to a maximum of 300 atm whereas in case of referred study [Prasad. S 2009], liquid yield increased to a higher value at 400 atm and later it got decreased.

### 3.3 Liquefaction of Waste N<sub>2</sub> Gases by PLHC

Waste N<sub>2</sub> rich gases from OPPOH which has a chemical composition as given by the Table 1 were considered to be a potential source for the liquefaction in this work. By setting the operating CDP at 150 atm that was confirmed from the preliminary study using pure N<sub>2</sub>, the effect of LCT was tested to obtain better liquid yield. As displayed in the figure 8, the highest yield of 11.12 Sm<sup>3</sup>/hr coupled with higher N<sub>2</sub> composition (volume fraction) of 0.8936 noted at LCT of 165 K and as LCT increased, both liquid yield and composition of N<sub>2</sub> were diminished to the lower levels of 0.17 Sm<sup>3</sup>/hr and 0.0053 respectively at 175K.

Since the composition of N<sub>2</sub> achieved at CDP of 150 atm and LCT of 165 K was not satisfactory, further change in CDP was made to examine improvement in composition and the corresponding liquid yield along with LCT. Therefore, the effect of CDP change was recorded in the range of 150 - 500 atm as shown in Table 2. When compared the yield and composition of liquid N<sub>2</sub> at different compressor discharge pressures, at 400 atm and -106.2°C maximum liquid product of 17.12 Sm<sup>3</sup>/hr with 90.33% (vol) of N<sub>2</sub> was recorded for the liquefaction of waste N<sub>2</sub> gases using an open loop PLC. Accordingly, at the same CDP and an LCT of 107.2 °C the liquefaction of waste N<sub>2</sub> gases performed on closed loop

PLHC and the maximum liquid yield measured as 168.2 Sm<sup>3</sup>/hr with an improved composition of 96.30 % of N<sub>2</sub> despite of slightly decrement in specific power consumption of about 3 % as mentioned in the table 3.

The composition of waste N<sub>2</sub> gases effects significantly on the operating compressor discharge pressure in the liquefaction cycle and its corresponding lower cooling temperature as displayed in the table4. In addition, the yield of liquid decreased slightly and to higher composition of N<sub>2</sub> achieved at a very high CDP. In other words, liquefaction of waste N<sub>2</sub> gases consume more than 3 times higher specific power than in the liquefaction of pure N<sub>2</sub> gases using precooled Linde's cycle

### 3.4 Application of Kapitza's cycle for the liquefaction of Pure N<sub>2</sub> gases

Modified Claude's cycle which is known as Kapitza's cycle with two heat exchangers along with a cooler considered for the liquefaction of N<sub>2</sub> source gases. On prior to the development of a cycle for the liquefaction of waste N<sub>2</sub> gases, liquefaction of pure N<sub>2</sub> gases was examined under the different conditions for understanding the effect of lower cooling temperature at a fixed compressor discharge pressure of 40 atm on the yield of liquid product in both open loop and closed loop Kapitza's cycles. As shown in figure 9, the higher liquid product yields of 156.6 and 9.632 Sm<sup>3</sup>/hr were recorded at an LCT of 128 K with and without recycling of non-liquefied gases respectively. At the temperatures lower than 128 K, liquid yield remained constant at 156.6 Sm<sup>3</sup>/hr for closed loop cycle whereas it gradually increased in open loop system.

### 3.5 Liquefaction of waste N<sub>2</sub> gases using Kapitza's Cycle (KC)

Kapitza's cycle contains two heat exchangers rather than three coolers in the

case of Claude's cycle. The compressed gases pass through a cooler and the first heat exchanger where it gets cooled to a fixed temperature of -53.2 °C and then a fraction of gas (x) diverted to the expander to perform some work (W<sub>T</sub>) and the rest is allowed to throttle through the second heat exchanger in which the lower cooling temperature (LCT) will be determined for the optimal liquid production. As shown in the table 5, liquefaction of waste N<sub>2</sub> rich gases in KC system were analyzed by both open loop and closed loop configurations at 40 atm of CDP and an LCT of -161.2 °C. Despite of achieving similar N<sub>2</sub> compositions, energy consumption per L of liquid produced was cut off by 12.5% in case of liquefaction using closed loop KC system.

**Figure 9.** Effect of LCT on Liquefaction of Pure N<sub>2</sub> in Kapitza's system at a CDP of 40 atm

**Table 5.** Comparison of Liquefaction of waste N<sub>2</sub> with Open loop and Closed loop KC systems

Parameter	Open loop KC	Closed loop KC
CDP (atm)	40	40
LCT (°C)	-161.2	-161.2
Liquid yield (Sm <sup>3</sup> /hr)	23.29	156.5
N2 Composition (vol fraction)	0.9652	0.9651
Energy consumption (kJ/L)	3796.5	3375

Further study focused on understanding the effect of change in compressor discharge pressure on the liquefaction of waste gases in the Kapitza's cycle. The change in CDP from 20 to 80 atm have showed significant fluctuations in LCT, liquid yield and N<sub>2</sub> compositions as demonstrated by the fig.10. It was distinguished that the CDP change in between 30 and 40 atm required typical alterations in LCT values ranges from 122 K to 102 K and a slightly improved N<sub>2</sub> purity

recorded at 40 atm while the liquid yield remained constant at both conditions. Although Kapitza's cycle mostly preferred at relatively lower pressures of about 7-10 atm for liquefaction of gases [Yilmaz.C et al 2019], it was lucid that the higher pressures, very similar to Claude's operating conditions [Smith. J.M et al 2001] that are about 30-40 atm are required to obtain better liquid fraction of waste N<sub>2</sub> gases.

**Figure 10.** The effect of alteration in CDP on the liquefaction of Waste N<sub>2</sub> rich gases using KC system

**Figure 11.** The effect of LCT on Liquefaction of Waste N<sub>2</sub> using Kapitza's Cycle at a CDP of 40 atm

Waste N<sub>2</sub> gases liquefied in Kapitza's Open loop system at a compressor discharge pressure of 40 atm to verify the effect of lower cooling temperature on liquid production and its N<sub>2</sub> composition. Highest liquid yield of 23.29 Sm<sup>3</sup>/hr obtained at 102 K with a high N<sub>2</sub> volume fraction of 0.9562

as depicted in figure 11. But both liquid yield and N<sub>2</sub> compositions have diminished to zero as LCT approaches to 140K. In other words, the second heat exchanger in the cycle has posed a problem by crossing the pinch limits for a LCT lower than 102 K.

**Table 6.** Performance indicators of PLC and KC systems applied for the Liquefaction of waste N<sub>2</sub> gases.

Parameter	Pure N <sub>2</sub> Liquefaction using PLHC	Waste N <sub>2</sub> gases Liquefaction using PLHC	Pure N <sub>2</sub> Liquefaction using KC	Waste N <sub>2</sub> gases Liquefaction using KC
CDP (atm)	400	400	40	40
LCT (°C)	-106.2	-107.2	-171.2	-161.2

### 3.6 Performance Analysis of Liquefaction Cycles

Liquefaction of waste N<sub>2</sub> gases using precooled Linde's cycle and Kapitza's cycle are compared with each other to assess their performance in terms of required operating conditions, fractional conversion of gases in to liquid, the rate liquid yield, purity of N<sub>2</sub> in the liquid product, coefficient of performance and specific energy

consumption in kJ/L. The plant simulation results of both PLHC and KC systems for the liquefaction of waste N<sub>2</sub> rich gases are summarized in the table 6. In both the cycles, pure N<sub>2</sub> liquefaction have shown higher energy consumptions with slightly lower liquid fractions. In other words, KC system evaluated by the improved COP<sub>act</sub> values with marginally recovered quality of N<sub>2</sub> in the liquid product. Inevitably, specific energy consumption decreased by 74 % in Kapitza's cycle when compared with

Precooled Linde's cycle for the liquefaction of waste N<sub>2</sub> gases.

S. Prasad [Yilmaz C. et al 2019] has obtained a maximum yield of 7.13 % and the specific energy consumption of 4843 kJ/L at 8 bars of CDP for pure N<sub>2</sub> liquefaction using Kapitza's cycle model studied using HYSYS<sup>®</sup> whereas in the present study at 40 atm it was optimized to attain 14.8 % of liquid yield with 3719 kJ/L of specific energy requirement. Therefore, increase in pressure has resulted with increased yield with optimal energy consumption.

### 3.7 Validation of Models Adapted

Liquefaction models applied in the present study have been validated with reported works [Yilmaz.C et al 2019] from the literature. As described in the table 7, primary performance indicators of the liquefaction cycles such as liquid fraction recovered and coefficient of performance (COP) of the systems were compared. COP values estimated in the present work are higher in both PLHC and KC systems used for the liquefaction of pure N<sub>2</sub> whereas the liquid yield has decreased marginally, yet the models developed are competitive. Since the present work majorly concerned about liquefaction of waste N<sub>2</sub> gases that emits from oxygen production plants using PSA technology, the liquid products obtained by the proposed models are validated with the products in the market [Schimdt. J 2023] as given in the table 8. Heat of vaporization and specific volume have deviated with slightly higher values in case of the proposed models whereas the rest of the properties are almost merged with available products in the market.

## 4. Conclusions

Many researchers have been focused on liquefaction of nitrogen from the air separation process but the liquefaction of

waste N<sub>2</sub> rich gases that are generated from the oxygen production plants have not yet taken much attention. In the context of that, this work aimed at utilization of such gases for the feasible production of liquid N<sub>2</sub> by developing most commonly practiced cryogenic cycles such as Precooled Linde-Hampson cycle and Kapitza's cycle. Liquefaction of Pure N<sub>2</sub> and waste N<sub>2</sub> rich gases were performed on aforementioned cycles to achieve optimal liquid fractions and improved N<sub>2</sub> compositions. When the systems are not facilitated with recycle (open loop) consumed higher specific energies while energy consumption has reduced significantly in the case of closed loop operation. Compressor discharge pressure and lower cooling temperature of the working fluid are two key parameters that play vital role in liquefaction of gases. Optimal liquefaction of Pure N<sub>2</sub> at 150 atm of CDP and -115.2 °C of LCT in PLHC system generated a liquid yield of 156.6 Sm<sup>3</sup>/hr along with a specific energy requirement of 4195.4 kJ/L. On the other hand, Liquefaction of Pure N<sub>2</sub> in Kapitza's system consume 3719 kJ of energy per L of liquid N<sub>2</sub> while producing the constant liquid yield because of lower CDP levels applied. Since the waste N<sub>2</sub> gases are comprised of different components, composition of nitrogen in the liquid has been given much attention for the model development. In the perspective of that, CDP levels altered to obtain better N<sub>2</sub> quality at the expense of quantity of the liquid. Thus at 400 atm and 40 atm of CDP values have generated the optimal liquid products of 168.2 and 156.5 Sm<sup>3</sup>/hr, besides the improved N<sub>2</sub> compositions of 96.3 % (vol) and 96.51% respectively. Nevertheless, PLHC consume 74 % more specific energy than Kapitza's cycle. Consequently, the Kapitza's cycle model developed proved to be a competitive system when compared with PLHC and other reported models in relation to the key performance indicators such as COP<sub>act</sub> of

0.8404 and a liquid fraction of 0.1488. Both the applied cycles produced similar liquid N<sub>2</sub> products in terms of physicochemical parameters and the properties match merely with the products in the market. However, developed models are constrained by the conditions applied and thermodynamic property packages selected etc., to achieve even more reliable system, attention must be paid for the development of enhanced cycles.

**Acknowledgements** The authors of this report gratefully acknowledge Mr. Mhreteab

Tesfay, the plant manager of Oxygen Production Plant of Orotta Hospital, Asmara for his persistent support in providing the needful information. Authors convey their gratefulness to Dr. Sujana Ramesh for her consistent support in developing the concept. ## CLUSTERING OF LOCALIZED ACOUSTIC EMISSION SOURCES BY THE DBSCAN ALGORITHM IN SEPARATORS

**Abstract:** *In this paper, the method for locating sources of acoustic emission by approximate calculation of potential coordinates using a grid superimposed on the area around the sensors that detected the wave was proposed. Various noises such as electromagnetic pulses and other external noises were removed from input data. The DBSCAN clustering algorithm was applied. The results were compared with the real state of the object under study after additional control. Analytical and practical research points to the possibility of using the presented method as a tool for determining the coordinates of defect development points and wave velocity.*

**Keywords:** *acoustic emission; location; defects; approximate calculation; clusterization; pressure vessel*

### 1. Introduction

When operating objects, it is very important to know their condition in order to avoid emergencies. Objects such as bridge columns, tanks for the transport of liquids, various structures in industry and many others are under constant loads during their use (Balagurin et al, 2020; Rastegaev et al, 2018; Nosov et al, 2017). There is a wide range of non-destructive testing methods that allow monitoring objects without destroying or dismantling it, such as xray inspection (Li et al, 2022), ultrasonic method (Smoqi et al, 2023) One of the most popular approaches is the acoustic emission (AE) method due to its accuracy and environmental friendliness. The AE method finds its application in various areas of technological process monitoring. For example, AE method is allowing to predict the structure of the metal during casting (Yaroslavkina et al, 2020), in (Ser'eznov et al, 2020) AE method was applied in aircraft construction, (Makhnutov

et al, 2020) applied AE methods to monitor composite fiber failures. The essence of the AE method is to detect the acoustic waves that arise in the object when defects occur during the operation of the object. To perform this method, AE sensors are installed on the investigated area of the object, then during the continuous loading of the object, various defects begin to appear in it: cracks, splits, material crumbling, and others. When they occur and during their growth, defects emit acoustic waves propagating through the object, which are recorded by sensors. Various parameters of the acoustic wave are recorded: amplitude, energy, time of arrival at the sensor, and many others. This is similar to complex systems with non-periodical dynamics (Pyko et al, 2018). Assessing the condition of an object can be very time consuming due to the size of the object under examination, so it is extremely important to reduce the areas that need to be checked by a specialist. Acoustic emission data sets are usually quite large, but the correlation of some of the

---

Email: [St054466@student.spbu.ru](mailto:St054466@student.spbu.ru)

parameters allows them to be reduced for more convenient and faster processing. Analysis of the data allows obtaining information about the defects in the object, their size, development progress and location. At the moment, many methods have been developed for analyzing acoustic emission data for various materials. However, there are still no universal automatic methods of analysis that give an accurate result without the participation of a specialist, therefore, this area is relevant to this day.

At the moment, there are quite a lot of different software for analyzing acoustic emission data, however, the operation of their methods is often hidden from users by trade secrets, and the algorithms used are often not updated along with the development of technologies. (Valen Systeme, Interunis, Diaton, etc.)

Analysis of large areas of the object under study takes a lot of time for specialists, so location and clustering methods are needed to indicate the areas in which defects are most likely to be located.

There are various approaches to source location: frequency and wave mode analysis (Jiao et al, 2008), laser-based reversal time concept (Park et al, 2012), analytical approach (Grigorieva et al, 2022). The result of the work of location methods are areas in which there will be a defect with the highest degree of probability. The location accuracy is influenced by many factors: the structure and shape of the object under study, its condition, the presence of cavities in it, design features, and much more. Different location methods take these factors into account to varying degrees.

After using location methods, various machine learning methods are often applied to the results obtained to determine the type of signal source and predict the further appearance of defects. In recent years, the field of machine learning has been developing rapidly, various approaches, such

as neural networks, clustering and classification algorithms, and others, allow you to get more and more accurate results. Clustering and classification algorithms are used to group data from located sources and form many types of defects. To date, there are many approaches to data clustering that differ in data type and clustering algorithm. Different algorithms have different advantages and disadvantages, as well as different requirements for input parameters. In (Feifei et al, 2011) K-means algorithm was used with cluster centers initializing with random uniform distribution to separate different types of AE signals sources. In (Calabrese et al, 2010) two different unsupervised clustering approaches were used to reduce set of data parameters and identify clusters of different AE signals: Kohonen map and principal component analysis. In (Feifei et al, 2012) DBSCAN (Density-based spatial clustering of applications with noise) (Ester et al, 1996) and K-means were applied to specific material 2.25Cr-1Mo experiment data and were used to separate different types of signals and to extract burst cracking signals. Solving the problem of localization and clustering of AE signals when examining thin-walled cylindrical vessels used for transporting and storing explosive combustible substances is relevant, as it helps to prevent their early failure, downtime, and even a technogenic or environmental disaster.

## 2. Primary Data Processing

When fixing the signals of acoustic emission to sensors on thin-walled vessels, the task goes from spatial to flat - to development of a cylindrical object on a plane. For analysis, the size of the object, the coordinates of the sensors placed on it, various signal parameters, the signal arrived on the sensor and others detected by sensors are used. Various design features of object such as

hatches, manholes, supports, unions and others are also taken into account. In Vallen, a single propagation velocity is set for all signals of the experiment, which does not take into account the design and material features, therefore, it is not used in the location and clustering algorithms of this work.

Among the unfavorable factors that have the most negative impact on the result of applying the method are noise-like signals that accompany all modes of operation of most industrial equipment, especially dynamically loaded equipment, and therefore noise is an integral part of any AE diagnostic signals. A high level of noise can lead to a failure in the correct operation of AE signal detectors, which is accompanied by: skips in signal registration; errors in calculating the time of their arrival; the appearance of false or displacement of real location events; incorrect assessment of the hazard class of acoustic sources and, in general, an incorrect assessment of the technical condition of dangerous production facilities. (автореферат , цитирование Игоря Анатольевича).

To solve the problem of detecting signals at the noise level and the possibility of recognizing from several, simultaneously acting acoustic sources, a method was chosen that is used by almost all major scientific groups involved in AE methods, namely: filtering (noise suppression) of the recorded signals in order to bring them to an impulse form for estimation by the amplitude threshold method.

In this work, filtering is carried out: by the amplitude threshold, by the number of sensors that recorded the signal, by the electromagnetic attribute. There are also technical limitations of AE sensors that do not capture the low frequency range below 40 kHz. These technical characteristics lead to forced filtering on a frequency basis. This work uses the VS150-RSC. The VS150-RSC is a piezoelectric AE sensor with integrated

Vallen Smart Line preamplifier. Its frequency response is characterized by a peak at 150 kHz

Acoustic emission data obtained during real experiments often contain a large number of various noises (human factor, electromagnetic oscillations, cosmic rays (Bonvech et al, 2022), etc.), which are also detected by sensors and significantly increase size of data set, thus it is essential to filter useful information from interference before further work (Davydova et al, 2015; Barat et al, 2010). There are various ways to separate signals from noise: Agletdinov et al, 2020; Rastegaev et al, 2020; Sedlak et al, 2009; Van Der Baan et al, 2015. In this paper, the recorded signals were filtered from obvious noises, the wave amplitude of which does not fall within the range of wave values from AE sources from 40 [dB] to 100 [dB], similarly to Balagurin et al (2020). Next, the signals that were recorded by no more than 4 sensors were removed. Considering the error of the equipment, it is impossible to establish any reliable location of AE sources using less than 4 sensors. The choice of this number of fixed sensors is due to the fact that with a smaller number of sensors, it will be impossible to solve the system of equations for finding the location of the signal source (the method with mathematical equations is used later to verify the reliability of the results obtained by the grid overlay method, see paragraph 3). On the other hand, if information from more than 6 sensors is taken into account, then the set of obtained solutions is sometimes truncated to an empty set due to the influence of data from the last distant sensors, and the more distant the sensor, the greater the error in the information it recorded. Thus, during preprocessing, it is necessary to limit ourselves to 4-6 nearest priority sensors. Then, hypothetical electromagnetic pulses were removed from the remaining data, which can also be captured by sensors from external objects and devices during the

experiment. These waves do not carry information about the state of the object and therefore also in this case refer to noise. Such data are distinguished by the fact that their fixation by sensors occurs almost simultaneously, since electromagnetic waves propagate at the speed of light. In the method, it was assumed that signals are electromagnetic, in which the difference in arrival at the sensors is less than 0.2 microseconds [μs]. After filtering the data, the method of approximate calculation on the grid was applied.

### 3. Grid overlay location method

#### 3.1. Problem Statement

When an acoustic wave propagates through an isotropic material, its velocity in all directions is almost the same. To locate the source, it is assumed that the wave is recorded by, at least, 4 sensors and its speed changes insignificantly. It is also assumed that the wave velocity lies within the range of possible values in the investigated object. The range of velocity values arises in view of the division of waves into Lamb and Rayleigh waves, which have different magnitudes. Depending on the distance from the source to the sensor, different waves of the same signal can be recorded (Grigorieva et al, 2022). Since the calculations take place on the development of the object, it is also necessary to consider the possibility of wave propagation through the edges of the plane along the shape of the object.

#### 3.2. Location method

The method is based on the approximate calculation of the possible coordinates of the wave source. Let several sensors record the wave. For first and second sensors in wave arrival order, the maximum distance at which the wave source can potentially be

relative to them is calculated.

$$d_{\max} = \frac{\sqrt{(x_2-x_1)^2+(y_2-y_1)^2}}{2} \quad (1)$$

where  $x_i, y_i$  - coordinates of the  $i$ -th sensor in order that recorded the wave.

Further, a grid with a certain step is superimposed on the area in which the sensors that recorded the wave are located within this distance. For every point grid, the condition of changing the velocity within the specified accuracy is checked:

$$|v_1 - v_2| < accuracy \quad (2)$$

where accuracy is predefined,

$$\begin{cases} v_1 = \frac{\sqrt{(x_2-x)^2+(y_2-y)^2} + \sqrt{(x_1-x)^2+(y_1-y)^2}}{t_2-t_1} \\ v_2 = \frac{\sqrt{(x_3-x)^2+(y_3-y)^2} + \sqrt{(x_2-x)^2+(y_2-y)^2}}{t_3-t_2} \end{cases} \quad (3)$$

After calculations for all grid vertices, a set of potential source points for different velocities is formed. Then, for each point of the resulting set, it is checked that among the three closest sensors to the given point there are at least 2 detected corresponding signal, allowing some error in the operation of the sensors.

**Table 1.** The set of possible AE source points for a single signal.

	x	y	speed
1	226.82	314.32	141.23
2	229.62	327.22	164.11
3	229.82	328.12	165.48
4	230.72	332.12	171.26

**Figure 1.** Grid overlay location method result

The Table 5 shows an example of data processing for a signal recorded by 5 sensors and shows the result of the proposed location method. The first and second columns indicate the most probable coordinates of the AE signal source, and the third column indicates the probable propagation velocity of this signal.

Figure 1 shows the result of the method for a single acoustic wave: the sensors that detected the wave are highlighted in green, red - set of potential points. At the last stage sets with more than 4 solutions (possible location points) were removed and the average value was calculated for each set of points.

After averaging the values in each set of points, a data set was obtained for further clustering.

#### 4. Data clusterization

For data clustering, the DBSCAN algorithm was chosen because it does not require knowing in advance the number of clusters, it gets the same result for the same data set, and it is resistant to outliers.

The clustering algorithm was applied to the previously obtained data set to determine the points clustering areas. The data obtained using the algorithm (Grigorieva et al, 2022) applied to the experimental data were also clustered to check the correctness of the location method.

The essence of the developed clustering method is to automatically calculate the ranges of characteristics characteristic of this particular object for one of the dangerous zones in which there is definitely a defect and, based on this, find the remaining zones of probable defects. For the method to work, the coordinates of the rectangle in which the required zone is located and the number of high-amplitude pulses in this rectangle are required. The number of pulses is determined empirically and varies from 3 to 10 depending on how damaged the object is,

based on (Gomera et al, 2014).

Since it is important to take into account not only the location of the points, but also the values of the amplitude and speed, for the correct formation of clusters. The selection of parameters was based on the following articles: Gomera et al, 2014; Yaroslavkina, 2018; Rastegaev et al, 2022.

The following metric was developed and applied:

$$f(i, j) = w_1 * l + w_2 * v + w_3 * a \quad (4)$$

$i, j$  – points in data set;  $w_1, w_2, w_3$  – weight coefficients of distance, speed and amplitude, respectively;

$$l = \sqrt{\left(\sum_{k=0}^n \frac{x_{ik}}{n} - \sum_{k=0}^m \frac{x_{jk}}{m}\right)^2 + \left(\sum_{k=0}^n \frac{y_{ik}}{n} - \sum_{k=0}^m \frac{y_{jk}}{m}\right)^2} \quad (5)$$

$$v = \left| \sum_{k=0}^n \frac{v_{ik}}{n} - \sum_{k=0}^m \frac{v_{jk}}{m} \right| \quad (6)$$

$$a = \min\left(\sum_{k=0}^n \frac{a_{ik}}{n}; \sum_{k=0}^m \frac{a_{jk}}{m}\right) \quad (7)$$

where  $x, y, v, a$  – averaged coordinates, speed, amplitude of points in sets which were described in section 3.2.,  $n, m$  - number of points in this sets.

For each of the parameters (distance, speed and amplitude) the corresponding threshold values were used to calculate the global epsilon used in the DBSCAN algorithm:

$$EPS = w_1 * eps_l + w_2 * eps_v + w_3 * eps_a \quad (8)$$

Weights  $w_1, w_2, w_3$  and epsilons  $eps_l, eps_v, eps_a$  are automatically calculated for each object of study based on data values. Automatic calculation of parameters for each object is increasing the accuracy of clustering.

After applying the algorithm, clusters with a large number of elements were removed from the resulting set of clusters, since in real cases such clusters are most likely signals received as a result of friction of object against a support that are not defects. Depending on how the experiment was conducted, clusters with 10-20 elements were considered as large.

As a result, the resulting clusters display areas on the object that are most likely to

have defects and that should be checked by a specialist.

## 5. Experiment

Data from several real experiments were used to test the methods. The formation and development of defects in the process of object loading were controlled by recording acoustic emission signals in real time with an Amsy-5 Vallen system (Germany) as in (Damaskinskaya et al, 2021). The technical features and characteristics of piezoelectronic sensors were given in paragraph 2. Software was developed for processing AE data using the proposed method. It is implemented on a modular basis, i.e., is a sequentially executed scripts of procedures: reading data, converting it, processing it according to the algorithm described above, unloading, clustering and visualization. The scripts are implemented in R, C# and Python programming languages.

### 5.1. Experiment 1

In the first experiment, the object of the study was a cylindrical pressure vessel: a separator made of steel 09G2S-17+08Kh13 with a height of 3200 [mm], an inner diameter of 2000 [mm] and a wall thickness of 12 [mm]. A hydraulic test was carried out: the vessel was filled with water and been under increasing pressure for 50 minutes. During the loading process, several cracks appeared in the object, which were recorded by specialists. The initial data contained 24579 lines of sensor data, of which 4856 remained after the primary data processing, making up 1061 signals.

### 5.2. Experiment 2

In the second experiment, the object of the study was a low-pressure separator made of steel 09G2S-12+08Kh13 with a height of 6674 [mm], inner diameter of 2400 [mm].

and wall thickness of 14[mm]. The capacity of the device - 31.0 [m3]. The same hydraulic test as in experiment 1 was carried out. The initial data contained 24579 lines of sensor data, of which 4856 remained after the primary data processing, making up 1061 signals.

### 5.3. Experiment 3

In the third experiment, the sensors were calibrated, during which AE events were simulated using a special device in different places of the object. By applying this device to the object under study, acoustic waves are simulated, similar to the waves that occur during the occurrence of defects, in order to fine-tune the AE. After applying the location method, 5 groups of AE sources were correctly identified, corresponding to the simulated signals. The initial data contained 431 lines of sensor data, of which 148 remained after the primary data processing, making up 37 signals.

## 6. Results

After applying the location method to first experiment data, the sets of possible AE source coordinates were calculated for 206 signals from the data set. For each of resulting signals, sets as in Figure 1 were received and displayed on a single location diagram in Figure 2.

Signals with 1 solution are shown in green, signals with 2 or 3 solutions – in blue, signals with 4 solutions are shown in red. It is important to note that the speed is calculated for each signal and for each solution individually. Thus, Figure 2 shows all the points of location of AE sources obtained by the method for the object under study. Moreover, the speeds of different AE signals are various. They are allowed to be different even for each of the four solutions of one signal.

Dot clustering areas coincide with the areas

indicated by specialists for additional control, due to the possible presence of defects in these areas.

**Figure 2.** Sets of the possible positions of AE sources.

It shows the correctness of the application of this method when method significantly reduces the areas of the object that should be checked by a specialist. In the future, it is planned to optimize the metric function in the DBSCAN algorithm for different types

of objects and apply more examining objects of this type. In the second experiment, after applying the location method 534 points dataset was obtained. As a result of clustering, 5 clusters were obtained.

In the second experiment, after applying the location method 534 points dataset was obtained. As a result of clustering, 5 clusters were obtained.

In Figure 3, the red rectangles mark the areas in which defects were actually found. Points with an amplitude of 40[dB] to 55[dB] are colored green, those with an amplitude of 55[dB] to 60[dB] are yellow, and red with an amplitude greater than 60[dB]. Points that did not fall into any cluster are colored black. Figure 3 shows that clusters were formed next to each problem area, and several clusters were formed near the area of the structural supports, where many AE signals often occur.

**Figure 3.** Experiment 1 clusterization result

In Figure 4 clusters of simulated AE sources shown as colored circles. The location of all sources was correctly determined and clustered.
